The NmF2 on MLAT versus MLT

Peak parameter reconstruction

Limberger et al., "Long-term comparison of the ionospheric F2 layer electron density peak derived from ionosonde data and Formosat-3/COSMIC occultations", J. Space Weather Space Clim., 5, A21 (2015). DOI: 10.1051/swsc/2015023

Data correspond to years 2006 - 2014

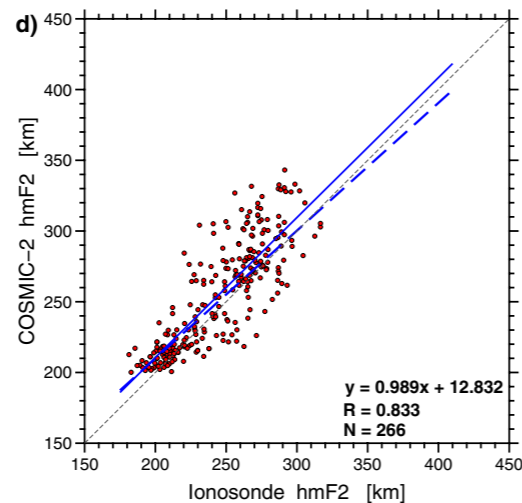

Separability hypothesis (Hernández-Pajares et al., 2000) has been used to invert RO data

Peak parameters reconstruction

American sector

Europe-African sector

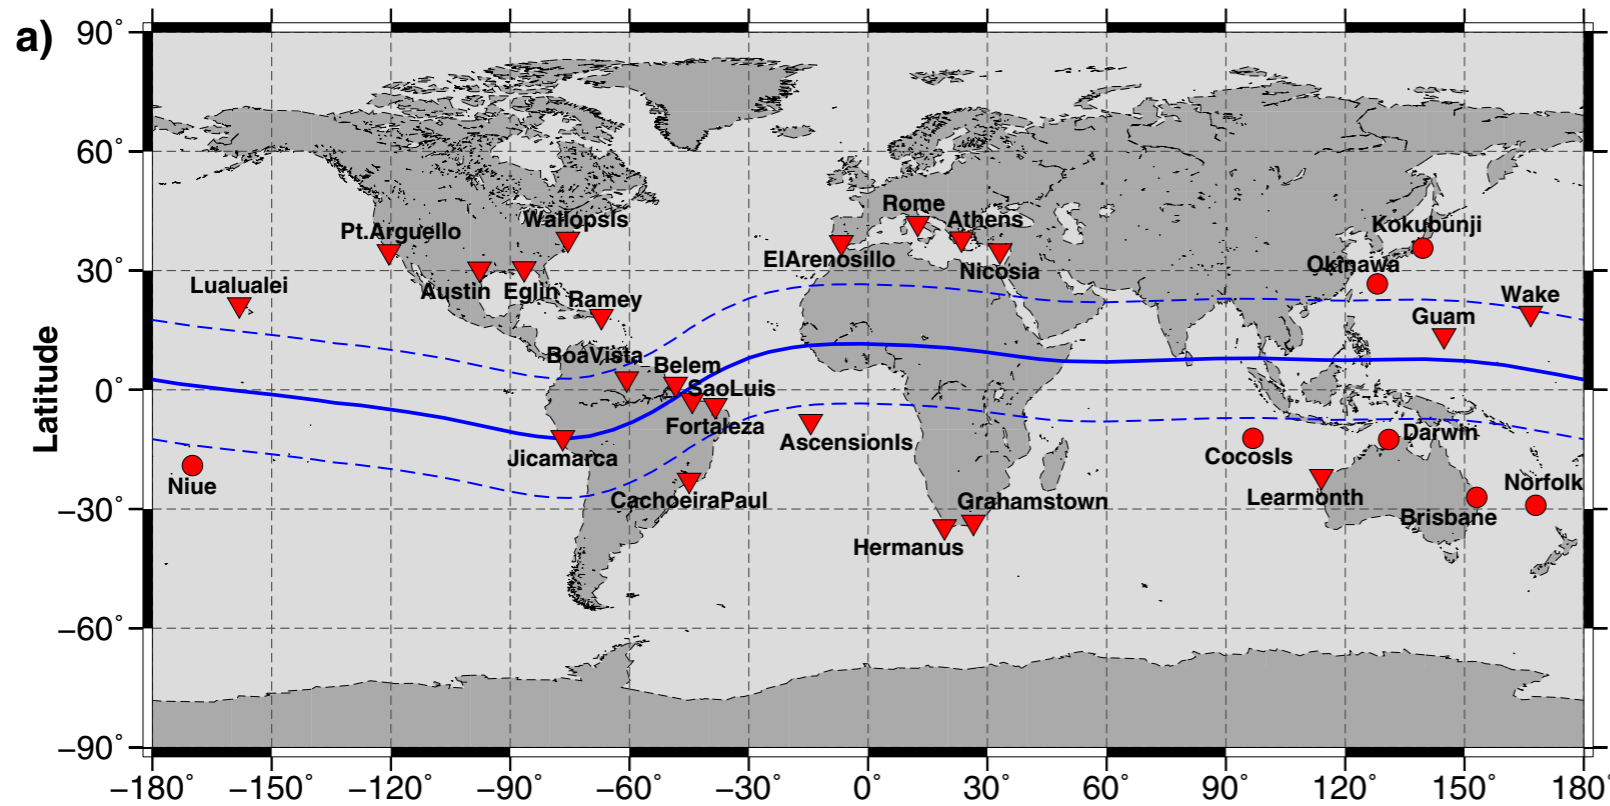

Asia-Pacific sector

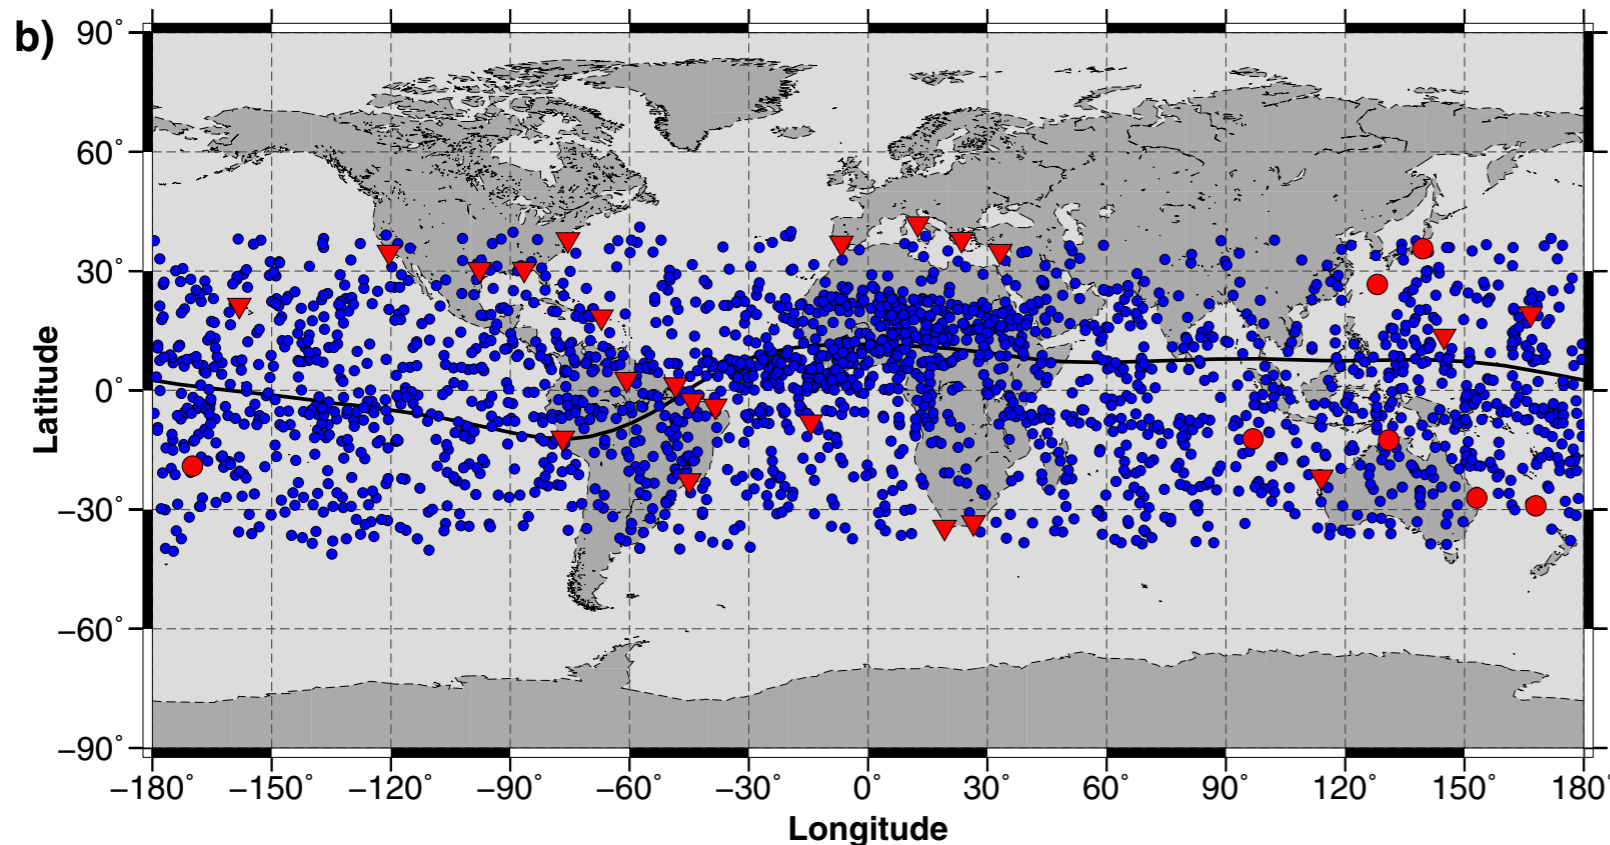

Scatter plots of the COSMIC-2 RO-based foF2 and hmF2 values against the corresponding ionosonde-derived ones with a separation to American, Europe-African, and Asia-Pacific longitudinal sectors. The solid blue lines show the best fit line, while the dashed blue lines show the best fit lines without zone separation.

from: Accuracy assessment of the quiet-time ionospheric F2 peak parameters as derived from COSMIC-2 multi-GNSS radio occultation measurements Iurii Cherniak, Irina Zakharenkova, John Braun, Qian Wu, Nicholas Pedatella, William Schreiner, Jan-Peter Weiss, Douglas Hunt J. Space Weather Space Clim. 11 18 (2021) DOI: 10.1051/swsc/2020080

COSMIC-2 footprint

(a) Geographical map with Digisondes (red triangle) and ionosondes (red circles) locations used in this study; lines show the magnetic equator and $\pm 15^\circ$ MLAT.

(b) Example of global distribution of the F2 peak points as derived from COSMIC-2 RO observations during 24 hr (25 January 2020).

Sporadic E

Effect of sporadic E clouds on GPS radio occultation signals

Z. Zeng¹ and S. Sokolovskiy¹

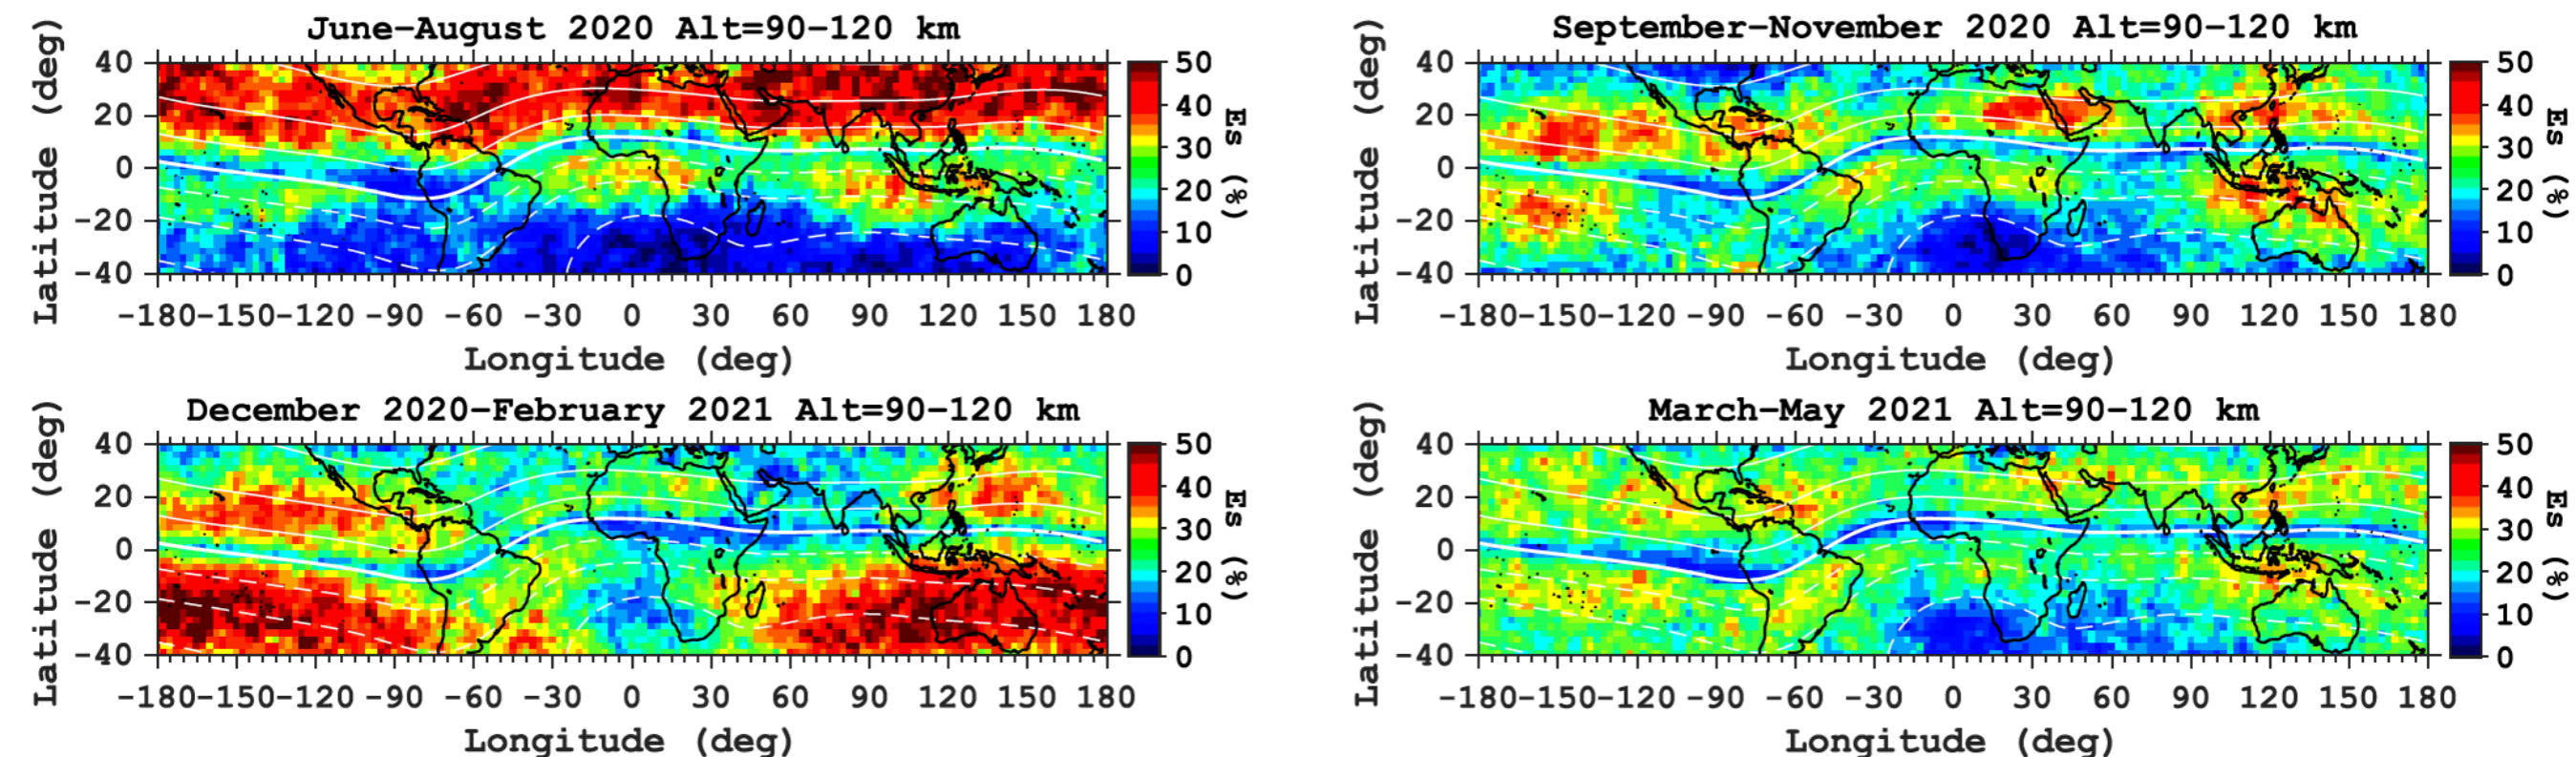

GEOPHYSICAL RESEARCH LETTERS, VOL. 37, L18817, doi:10.1029/2010GL044561, 2010

Distributions of the Es cloud events in COSMIC data from July 2009

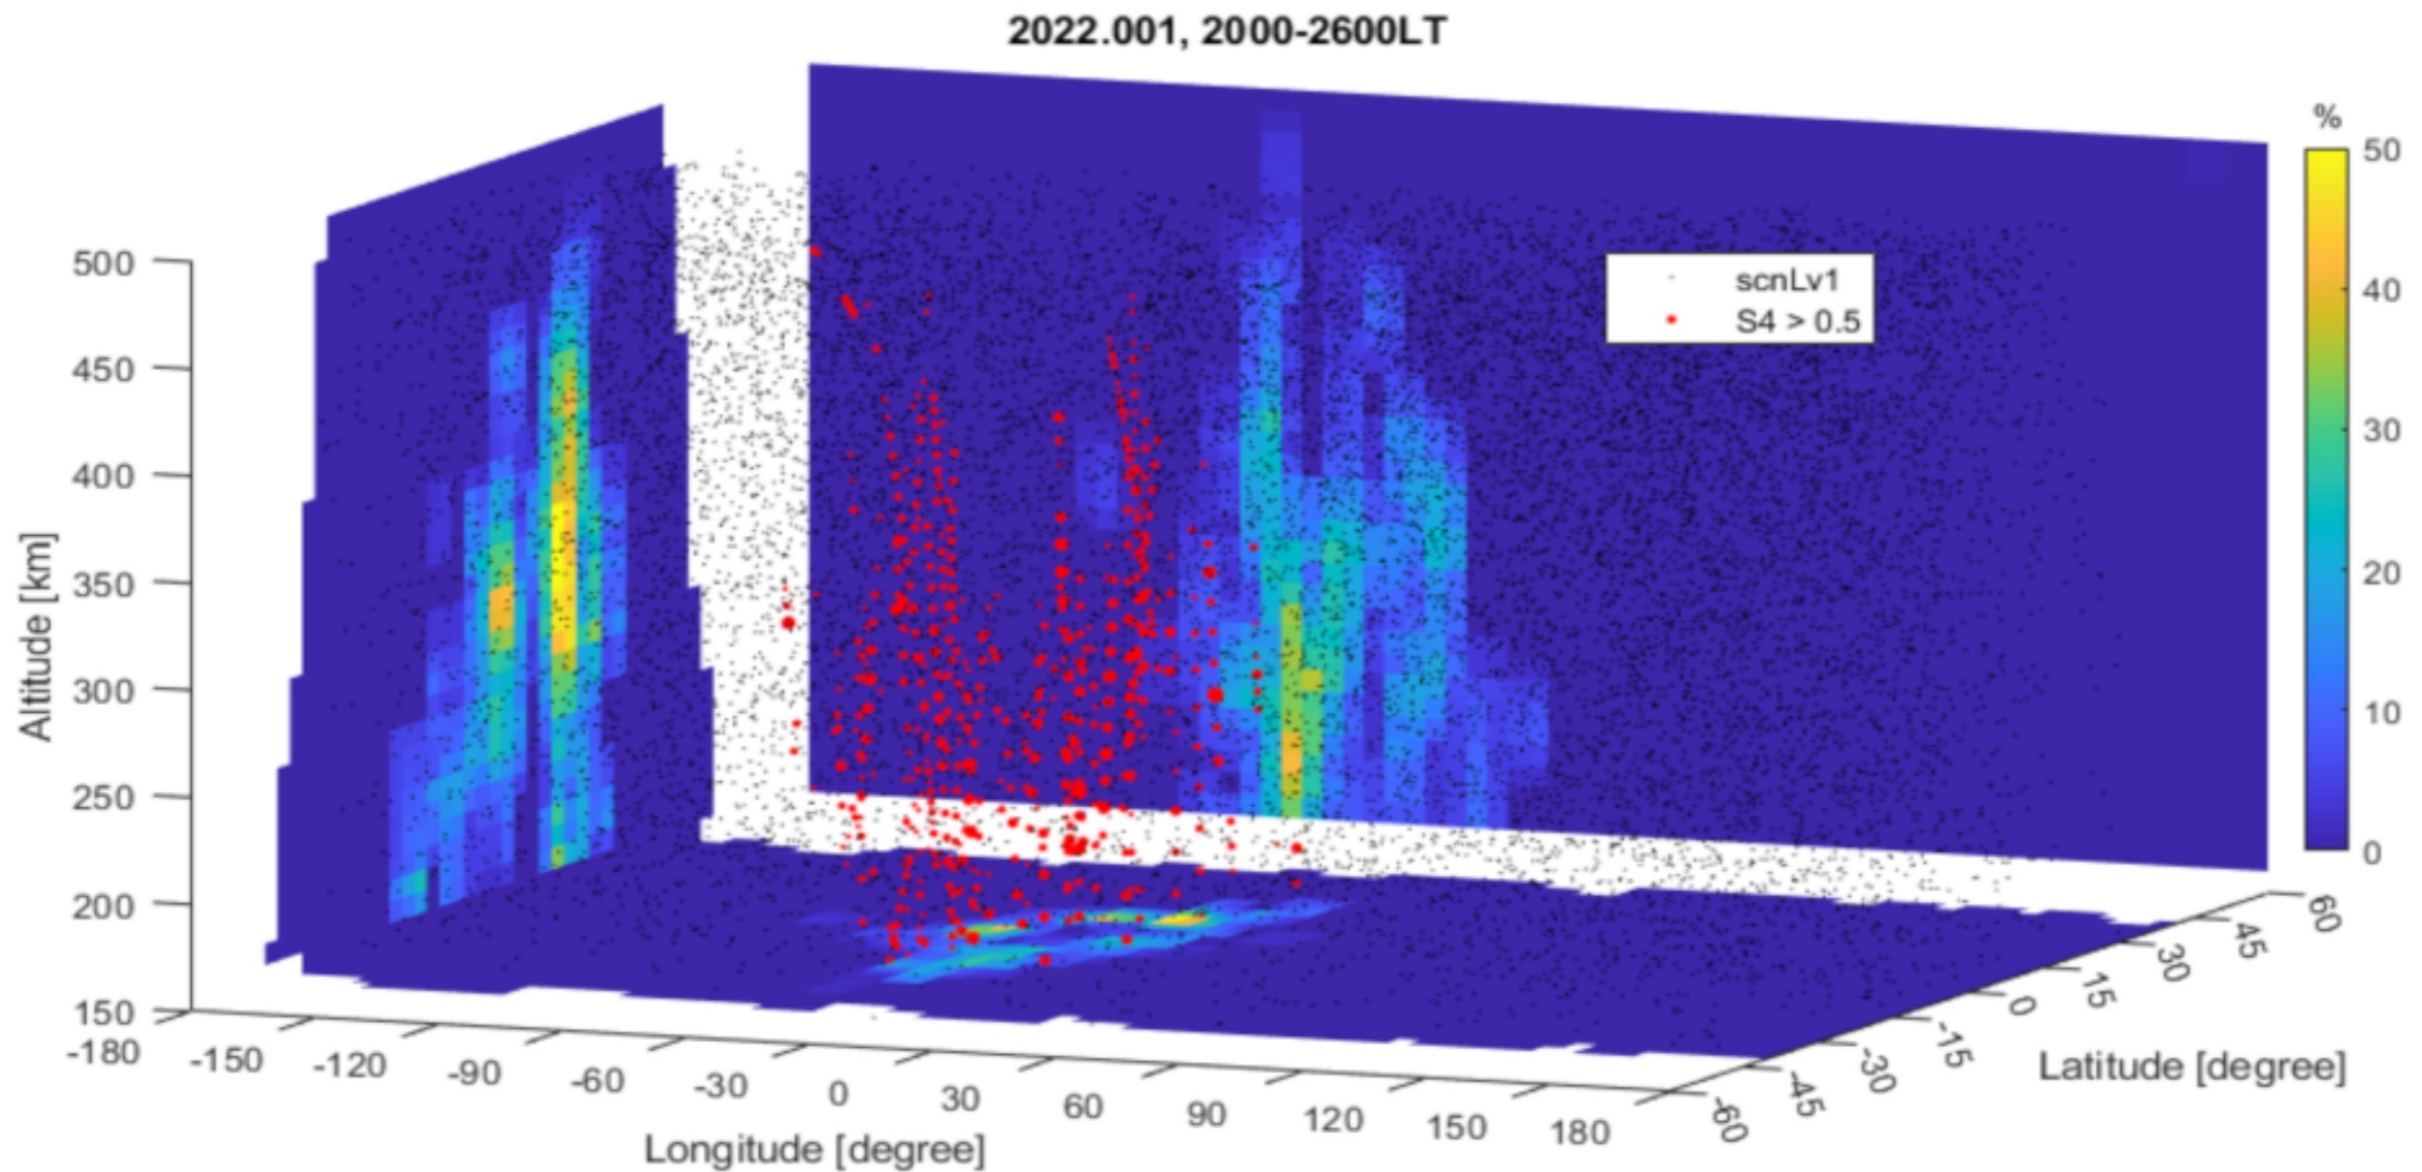

Sporadic E

The occurrence rate of sporadic E as derived from COSMIC-2 radio occultation data at 90–120 km during June–August 2020 (upper left), September–November 2020 (upper right), December 2020–February 2021 (lower left), and March–May 2021 (lower right).

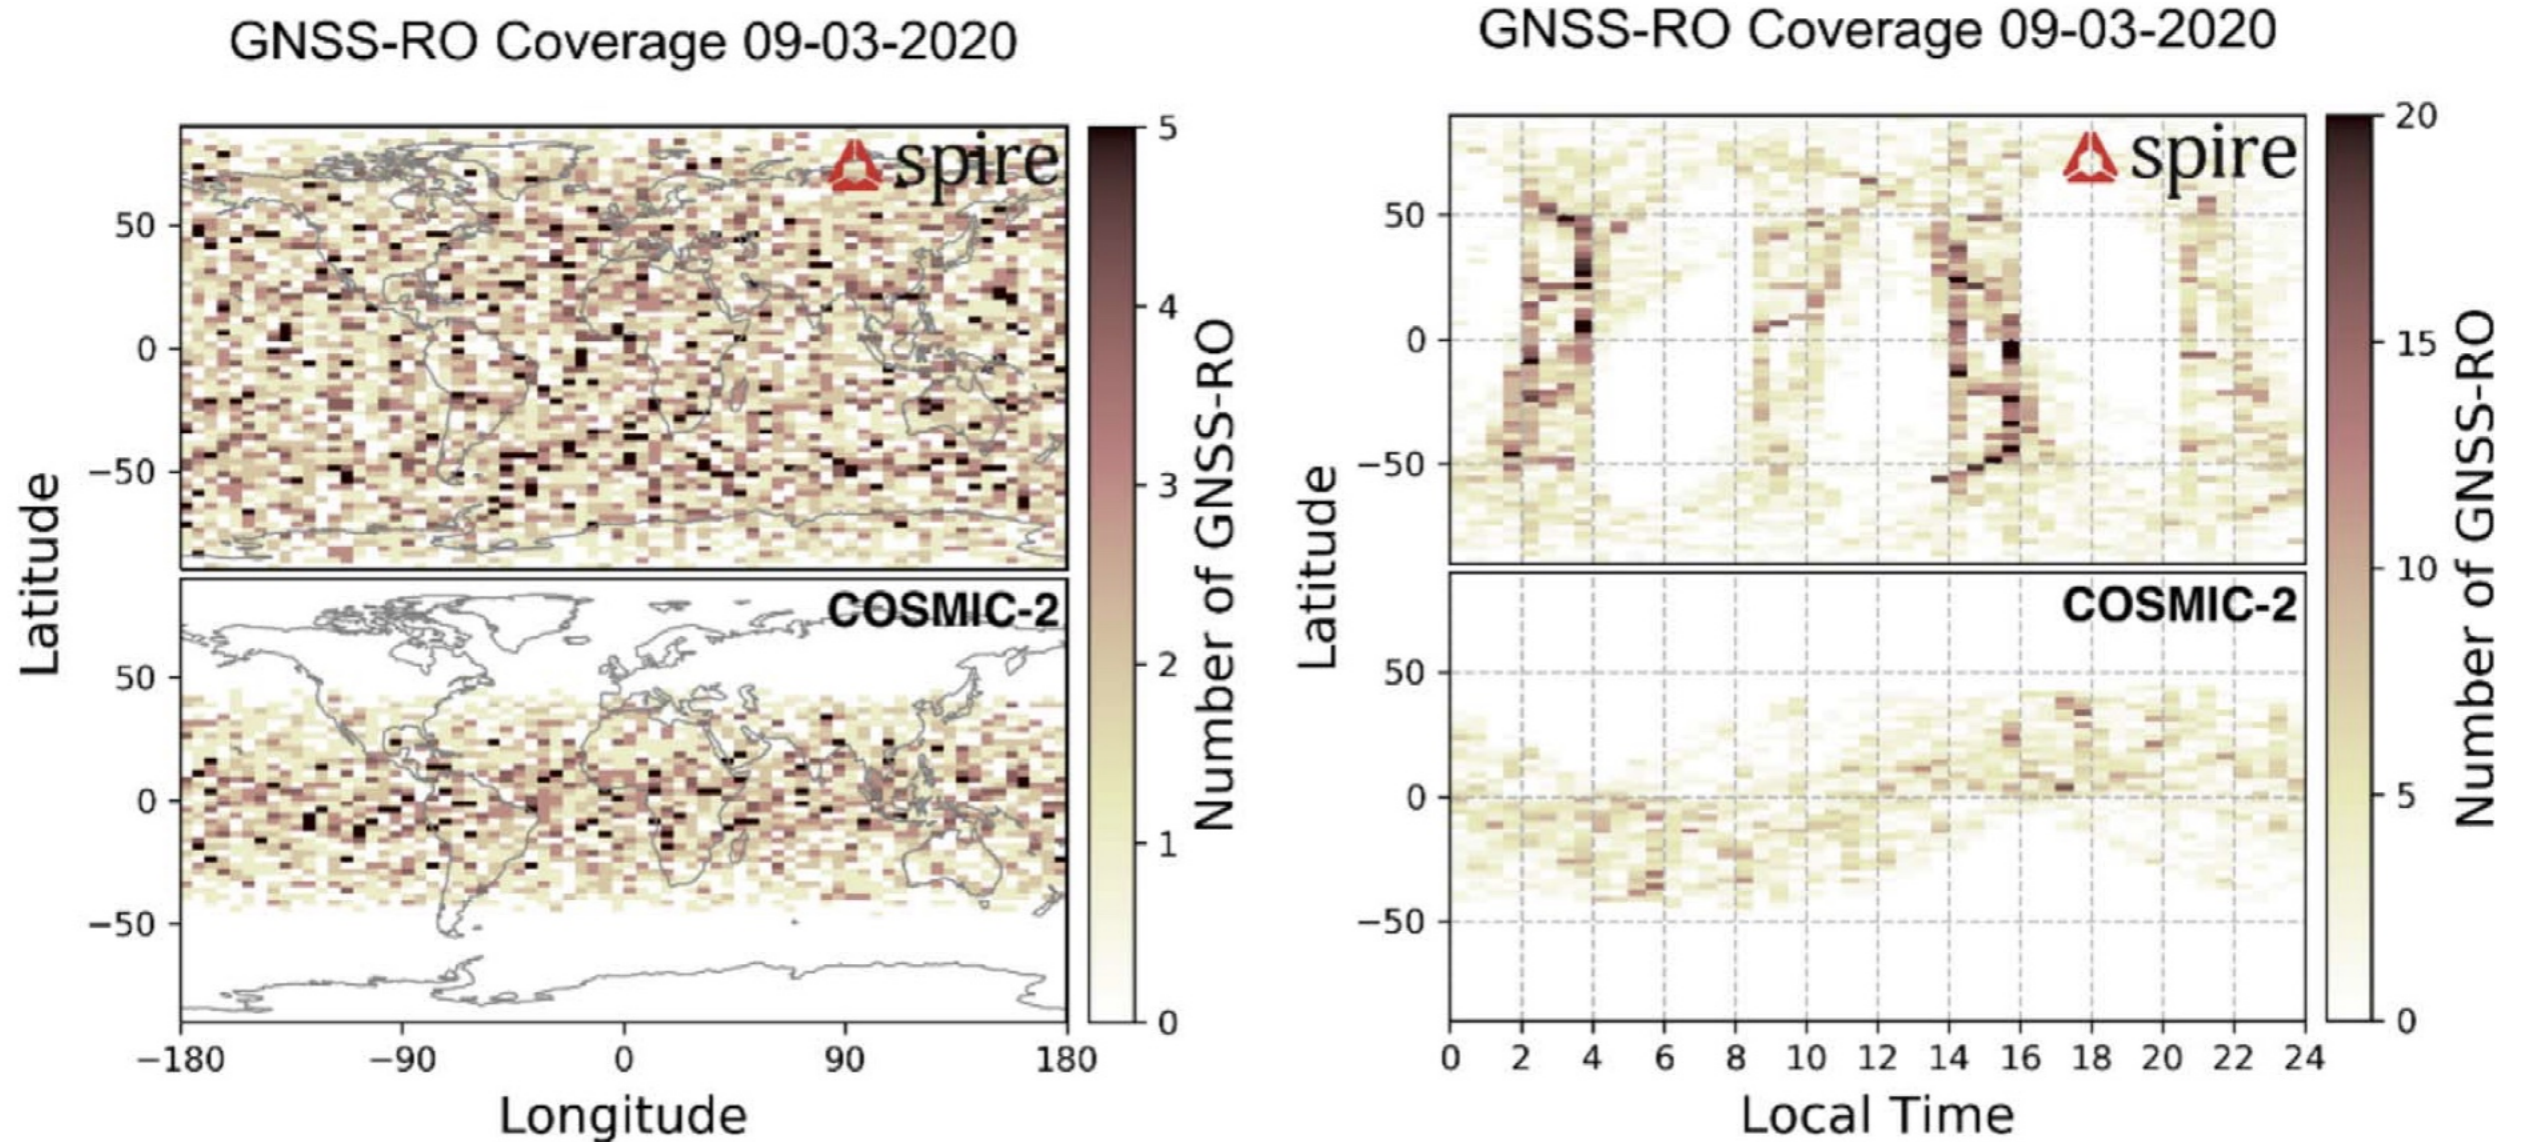

from: Yamazaki, Y., Arras, C., Andoh, S., Miyoshi, Y., Shinagawa, H., Harding, B. J., et al. (2022). Examining the wind shear theory of sporadic E with ICON/MIGHTI winds and COSMIC-2 Radio 2 occultation data. *Geophysical Research Letters*, 49, e2021GL096202. <https://doi.org/10.1029/2021GL096202>

Scintillations (COSMIC-2)

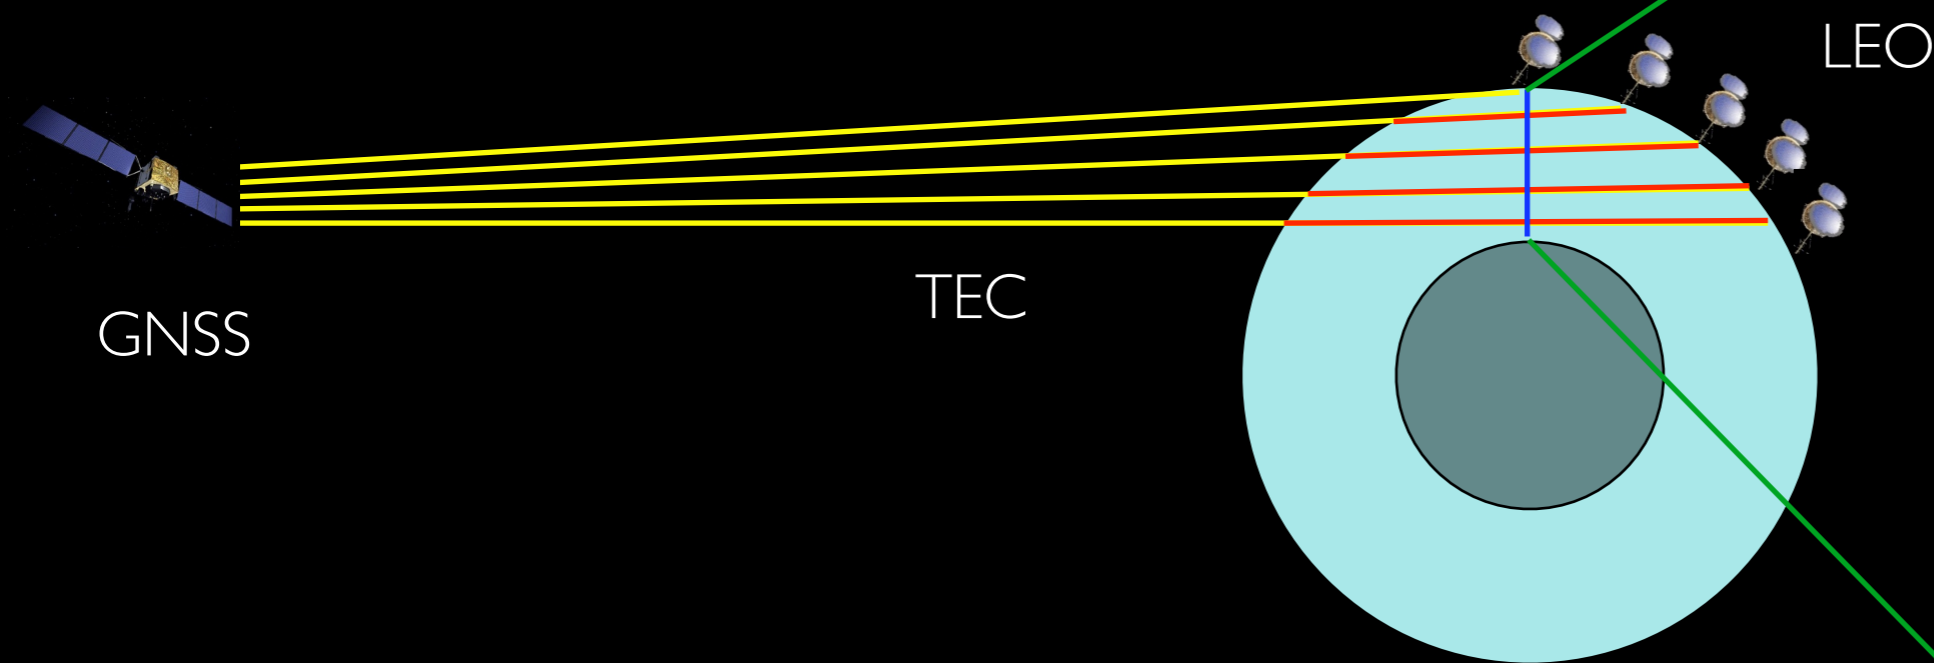

Distribution of nighttime intense scintillation ($S4\text{-index} > 0.5$). The color maps indicate the occurrence of intense S4 (red solid dots) in latitudinal (rear diagram), longitudinal (side diagram), and altitudinal intersections (bottom diagram) during 2000 LT to 0200 LT of 2022.001 to 2022.002 (from Liu et al., 2022).

Spire Constellation

One day of RO coverage for the Spire constellation and COSMIC-2 for 9 March 2020. The left panel shows the geographic distribution over the day, while the right panel shows the distribution with local time. Gaps are apparent in the local time distribution due to the limited number of orbital planes (from Angling et al., 2021).

GNSS RO data inversion

The Onion Peeling algorithm

- The “Onion Peeling” algorithm is a procedure that permits to compute a vertical electron density profile if the slant TEC from a LEO to a GPS satellite are available for an occultation event.
- Since the ray bending in the ionosphere is small enough, the straight-line propagation from GPS to LEO satellites is assumed for the GPS signals.
- As required by the inversion technique adopted, the spherical symmetry for the electron density of the ionosphere has been assumed.
- To compute the (calibrated) TEC in the shell determined by the LEO orbit, excess phase measurements at L1 and L2 GPS frequencies during one occultation event are used:
$$\text{uncalibrated_TEC[TECU]} = 9.52 * (\text{delayL1[m]} - \text{delayL2[m]}).$$

The Onion Peeling algorithm

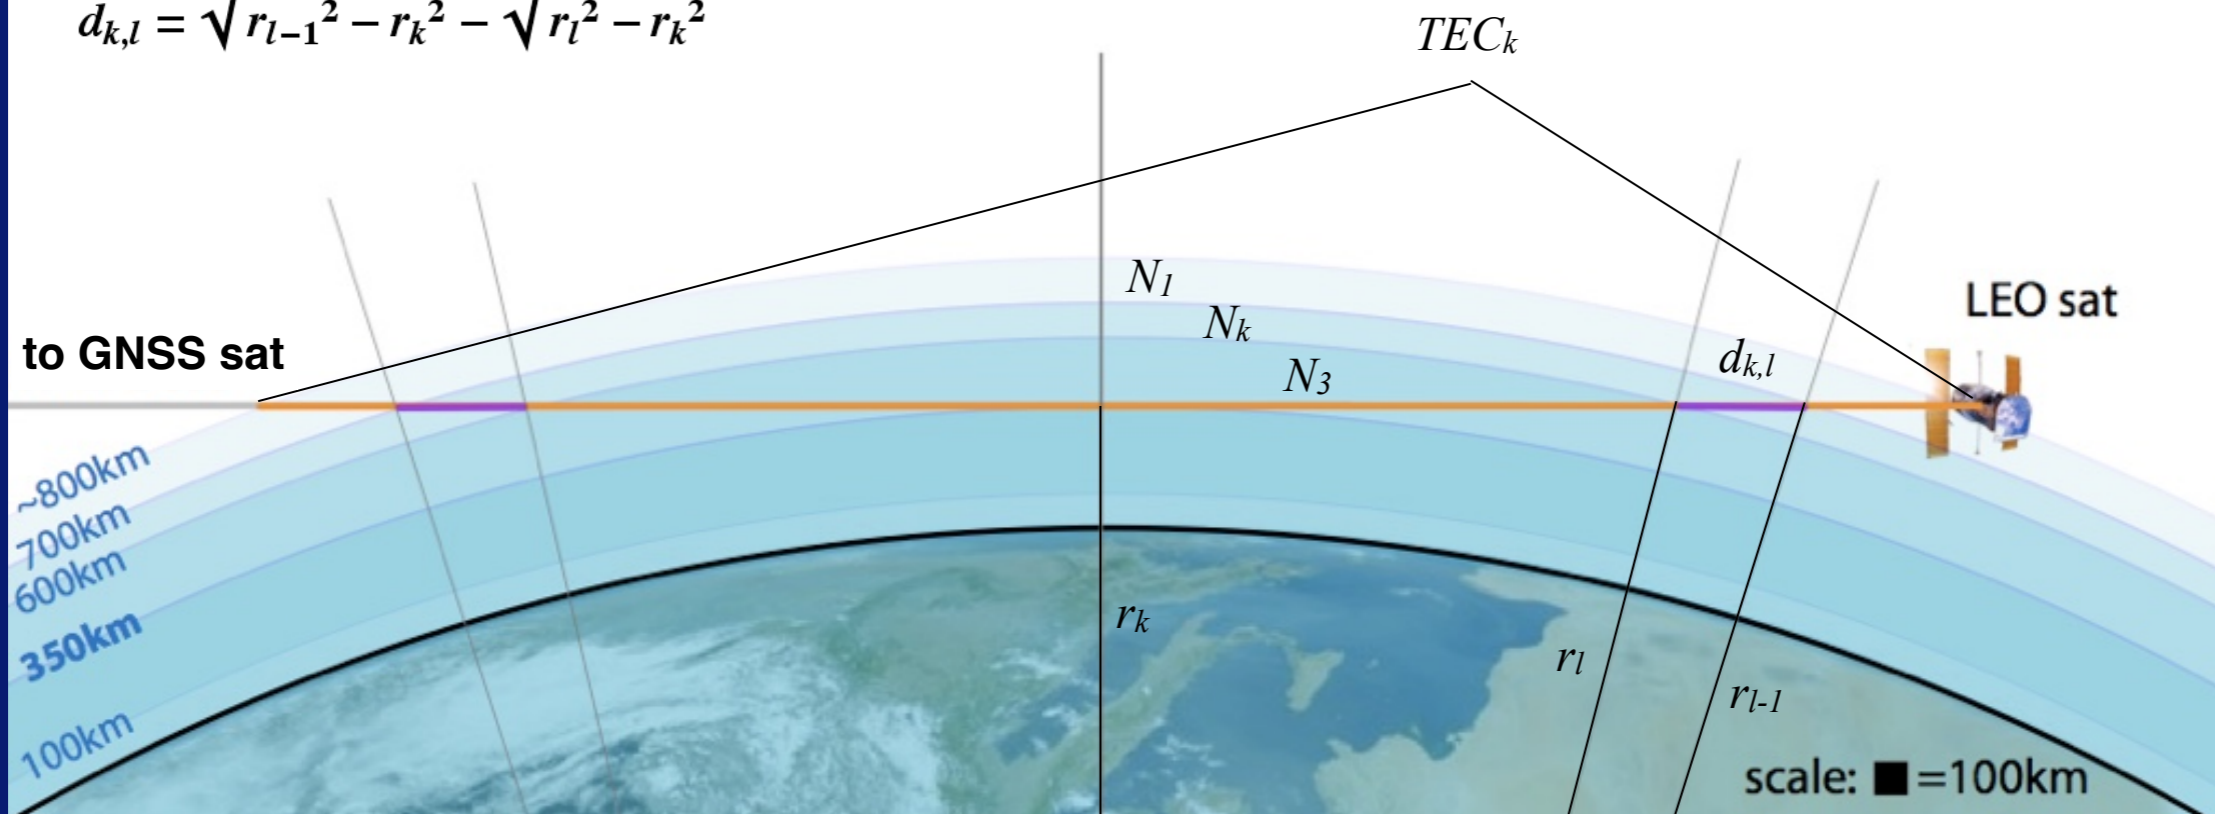

GNSS sat

scale: ■ = 1000km

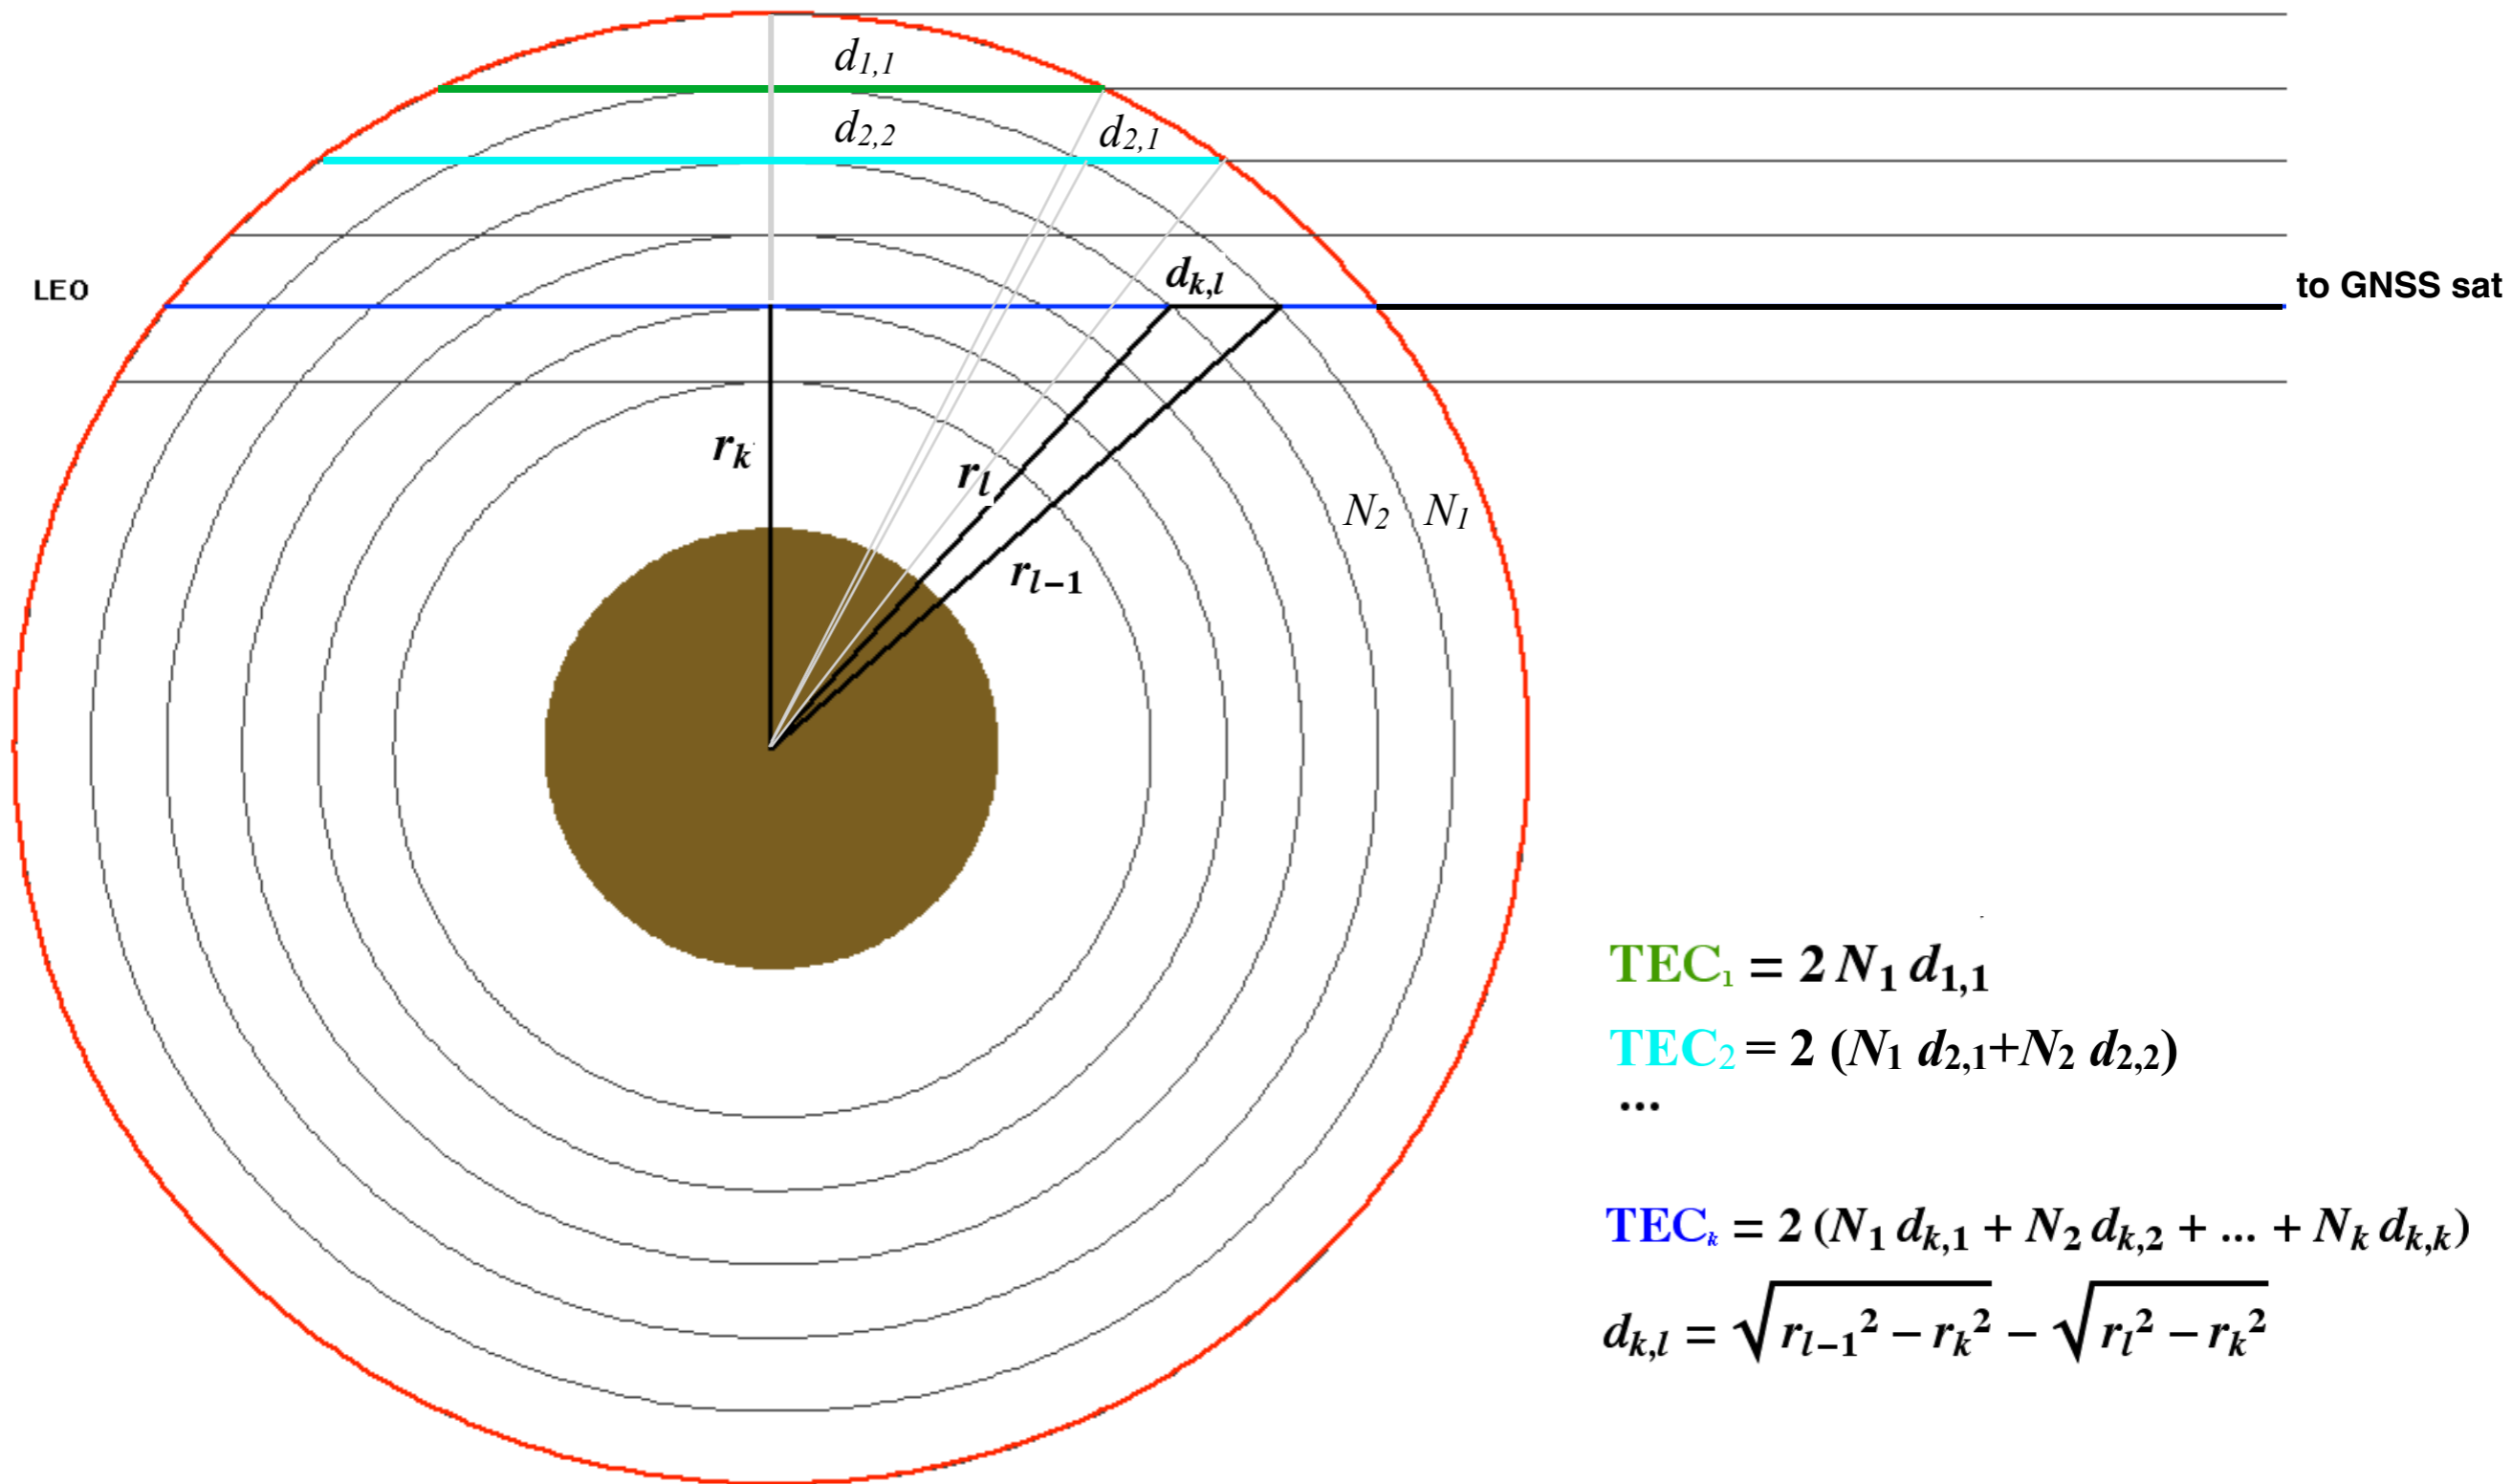

$$TEC_k = 2 (N_1 d_{k,1} + N_2 d_{k,2} + \dots + N_k d_{k,k})$$

$$d_{k,l} = \sqrt{r_{l-1}^2 - r_k^2} - \sqrt{r_l^2 - r_k^2}$$

scale: ■ = 100km

The Onion Peeling algorithm

$$\text{TEC}_1 = 2 N_1 d_{1,1}$$

$$\text{TEC}_2 = 2 (N_1 d_{2,1} + N_2 d_{2,2})$$

...

$$\text{TEC}_k = 2 (N_1 d_{k,1} + N_2 d_{k,2} + \dots + N_k d_{k,k})$$

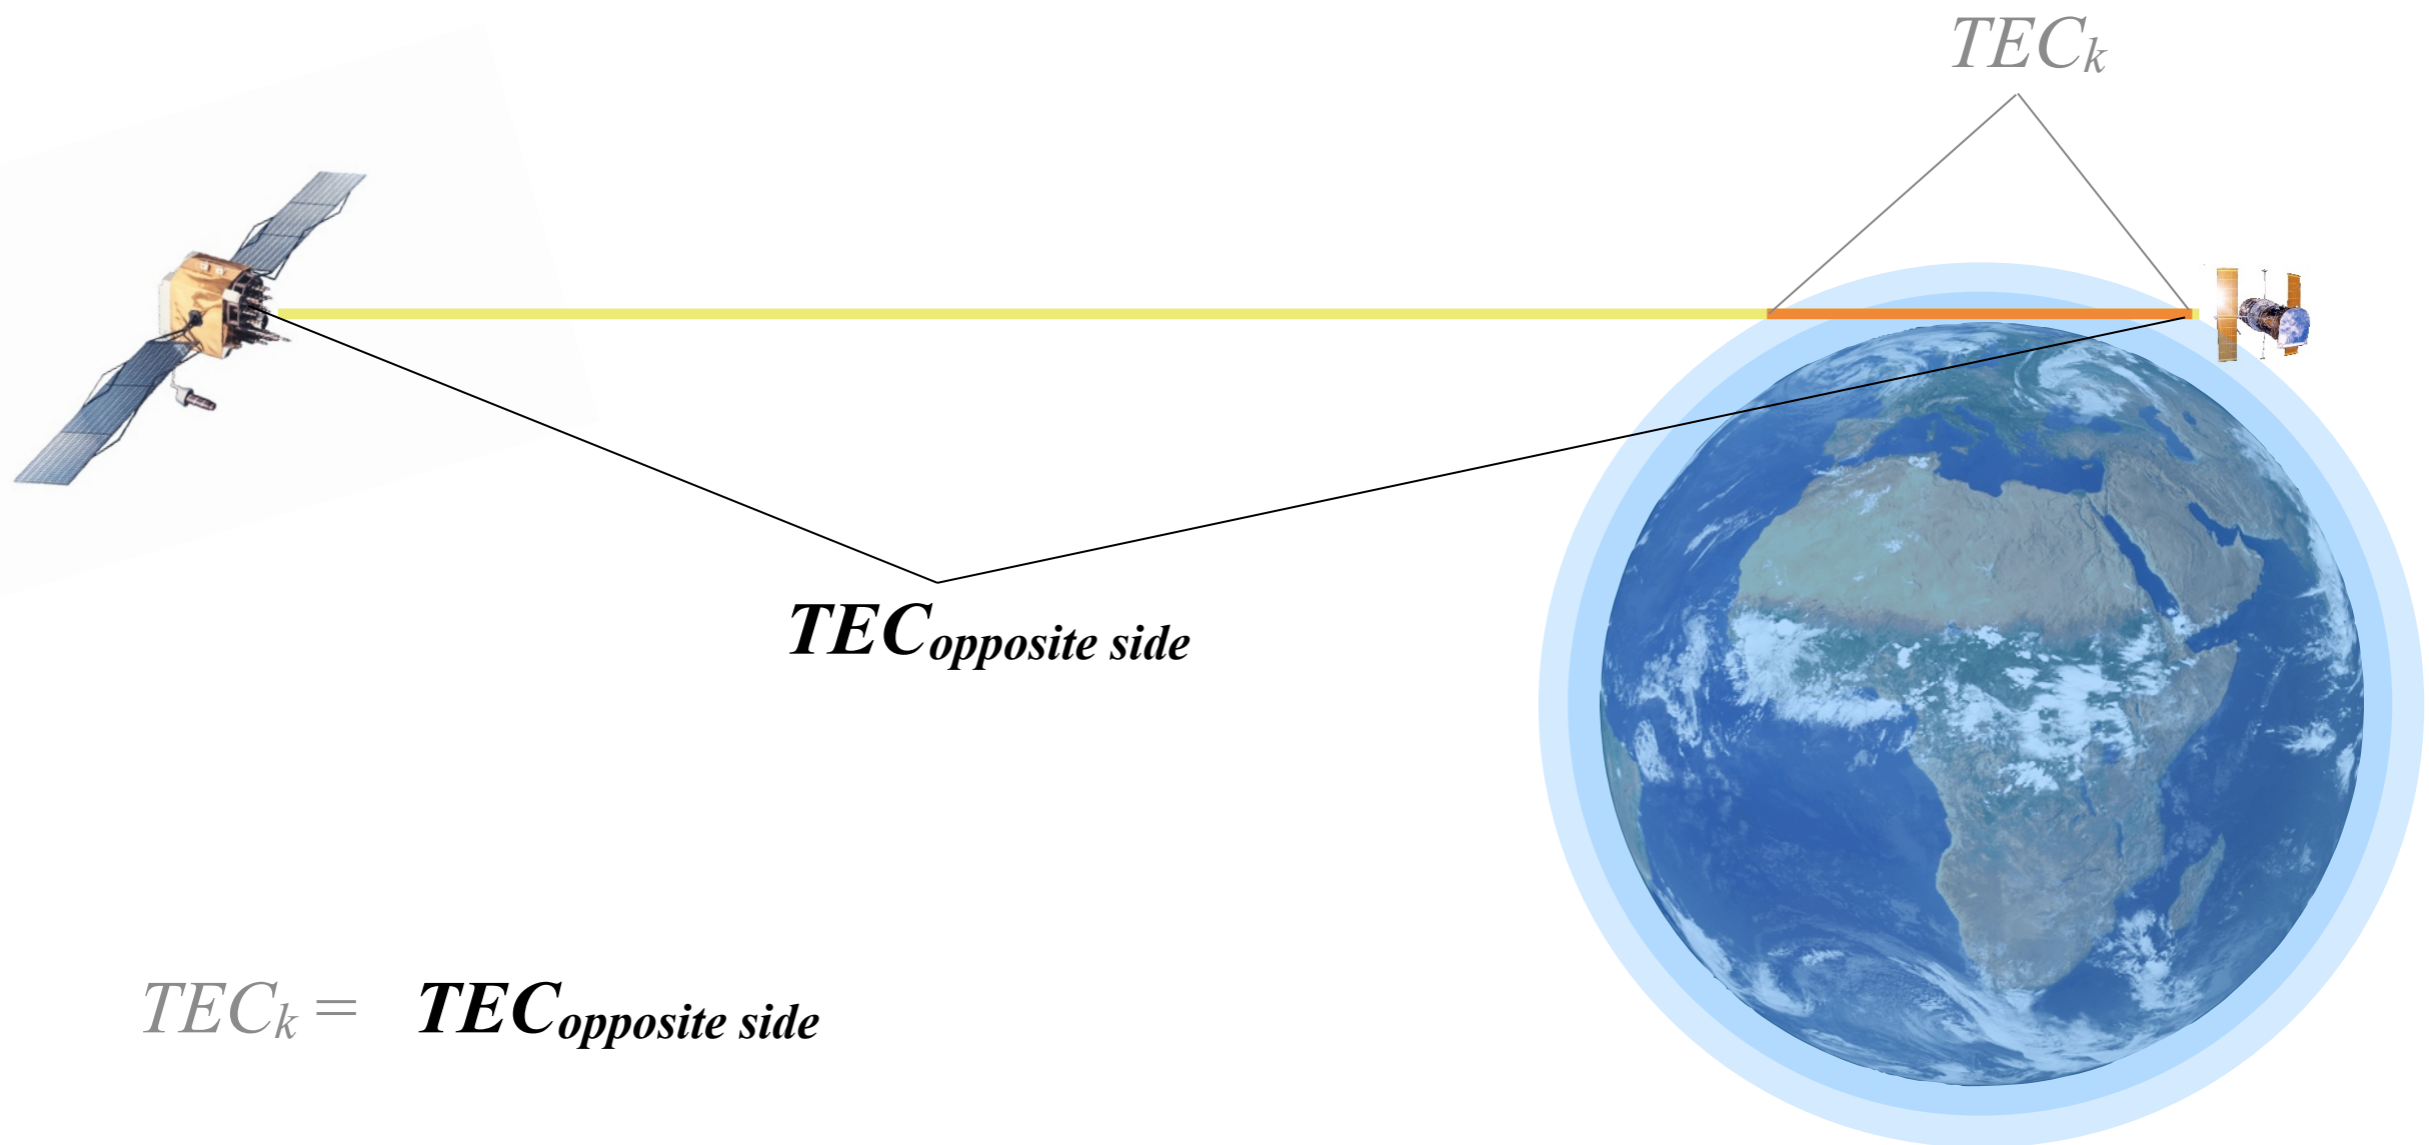

$$d_{k,l} = \sqrt{r_{l-1}^2 - r_k^2} - \sqrt{r_l^2 - r_k^2}$$

TEC calibration

$TEC_k =$

TEC calibration

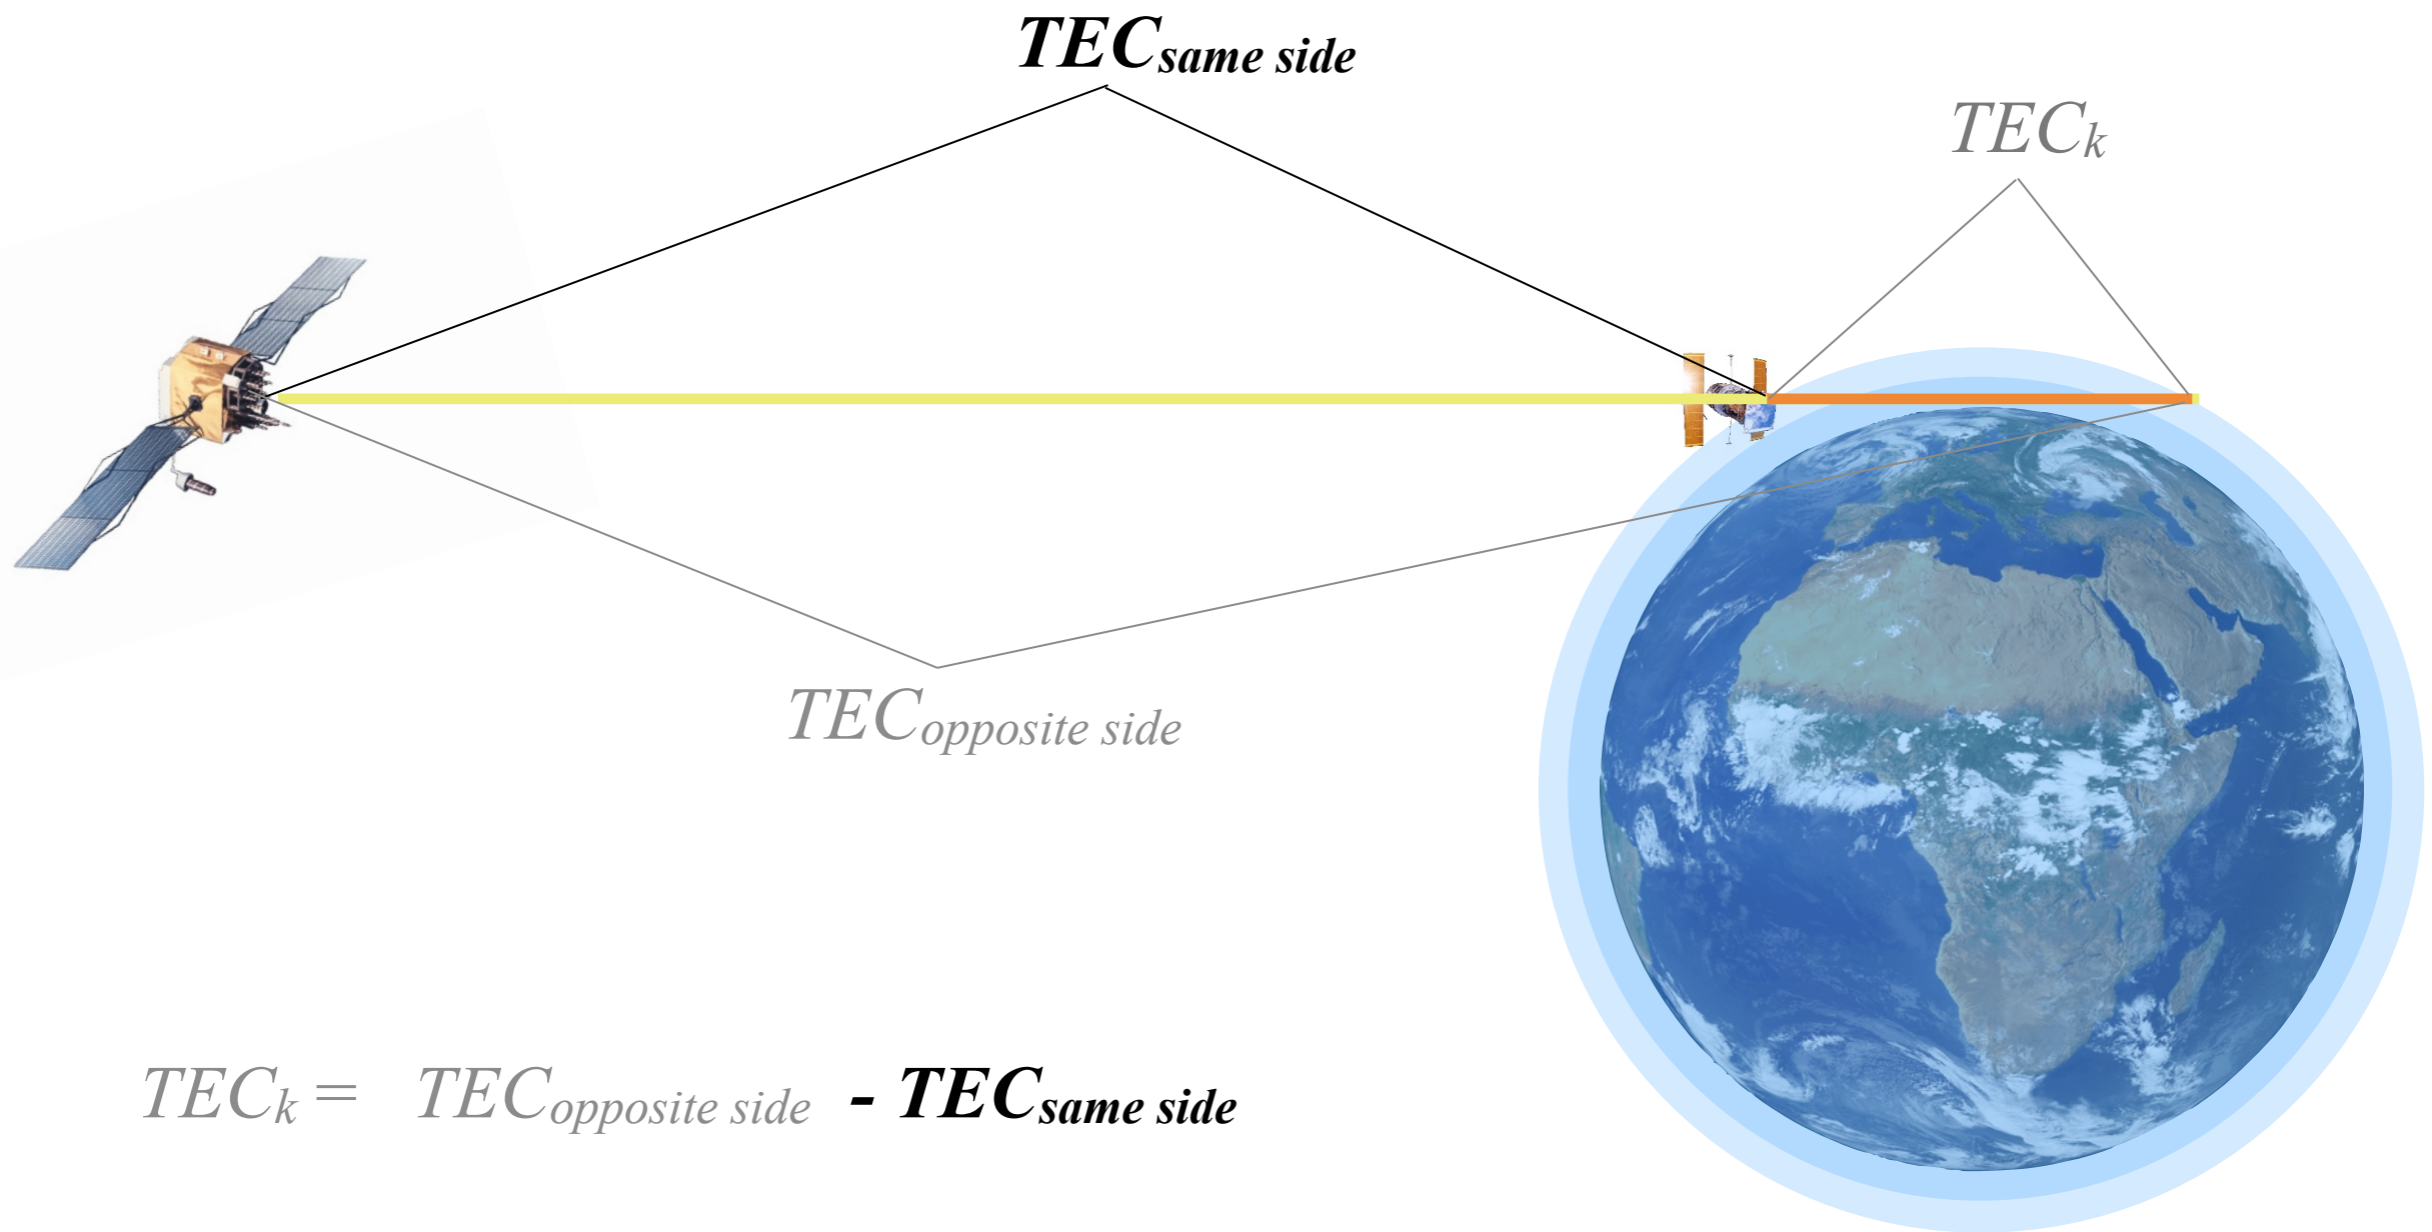

$$TEC_k = TEC_{opposite\ side}$$

TEC calibration

$$TEC_k = TEC_{opposite\ side}$$

TEC calibration

$$TEC_k = TEC_{opposite\ side} - TEC_{same\ side}$$

TEC calibration

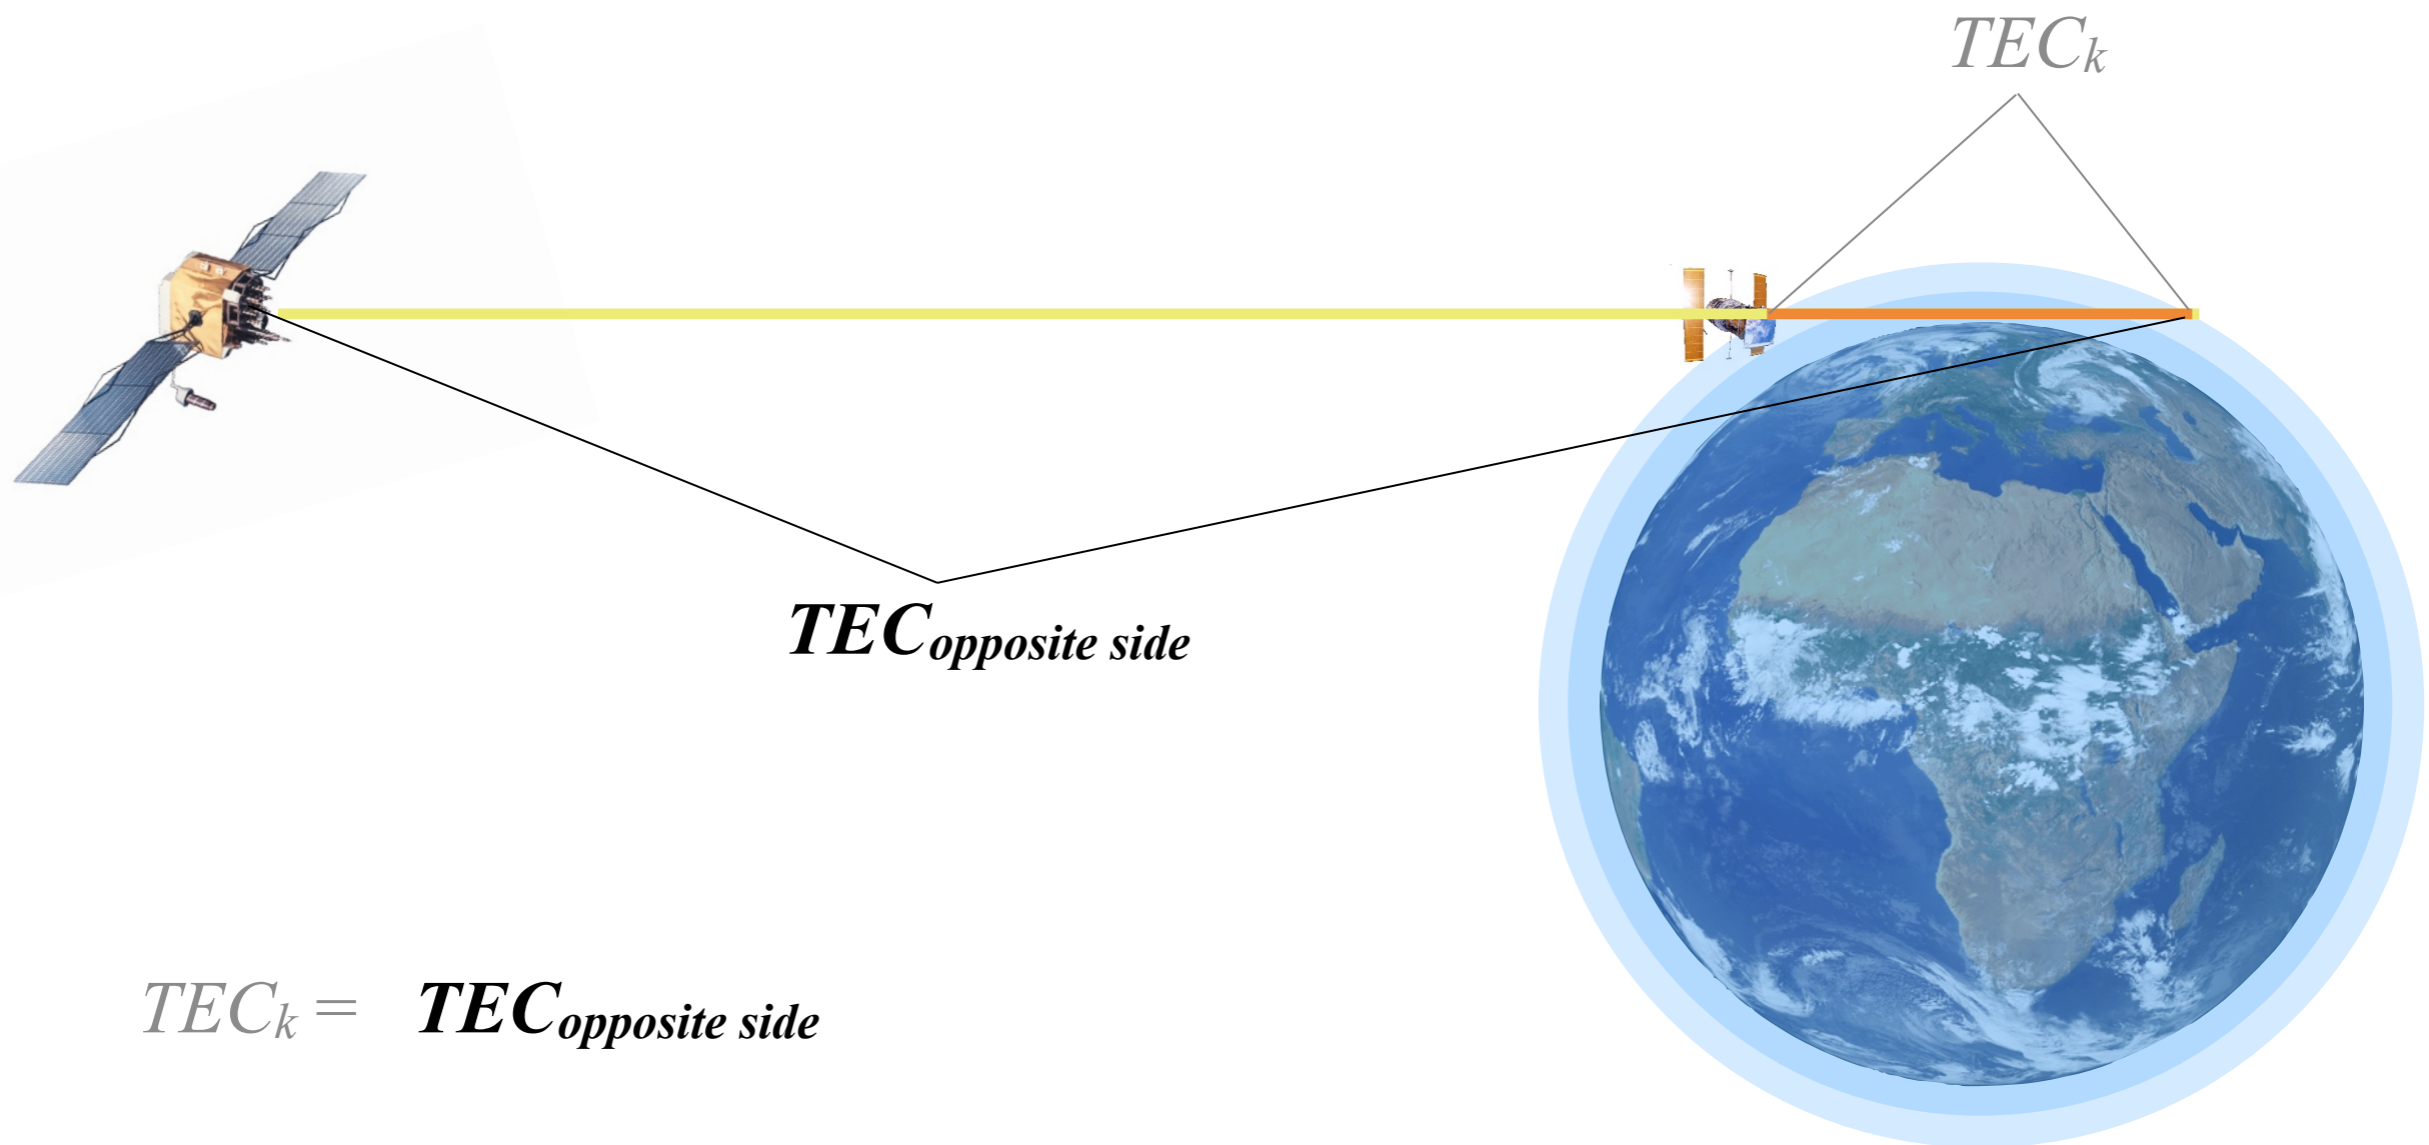

$TEC_k =$

TEC calibration

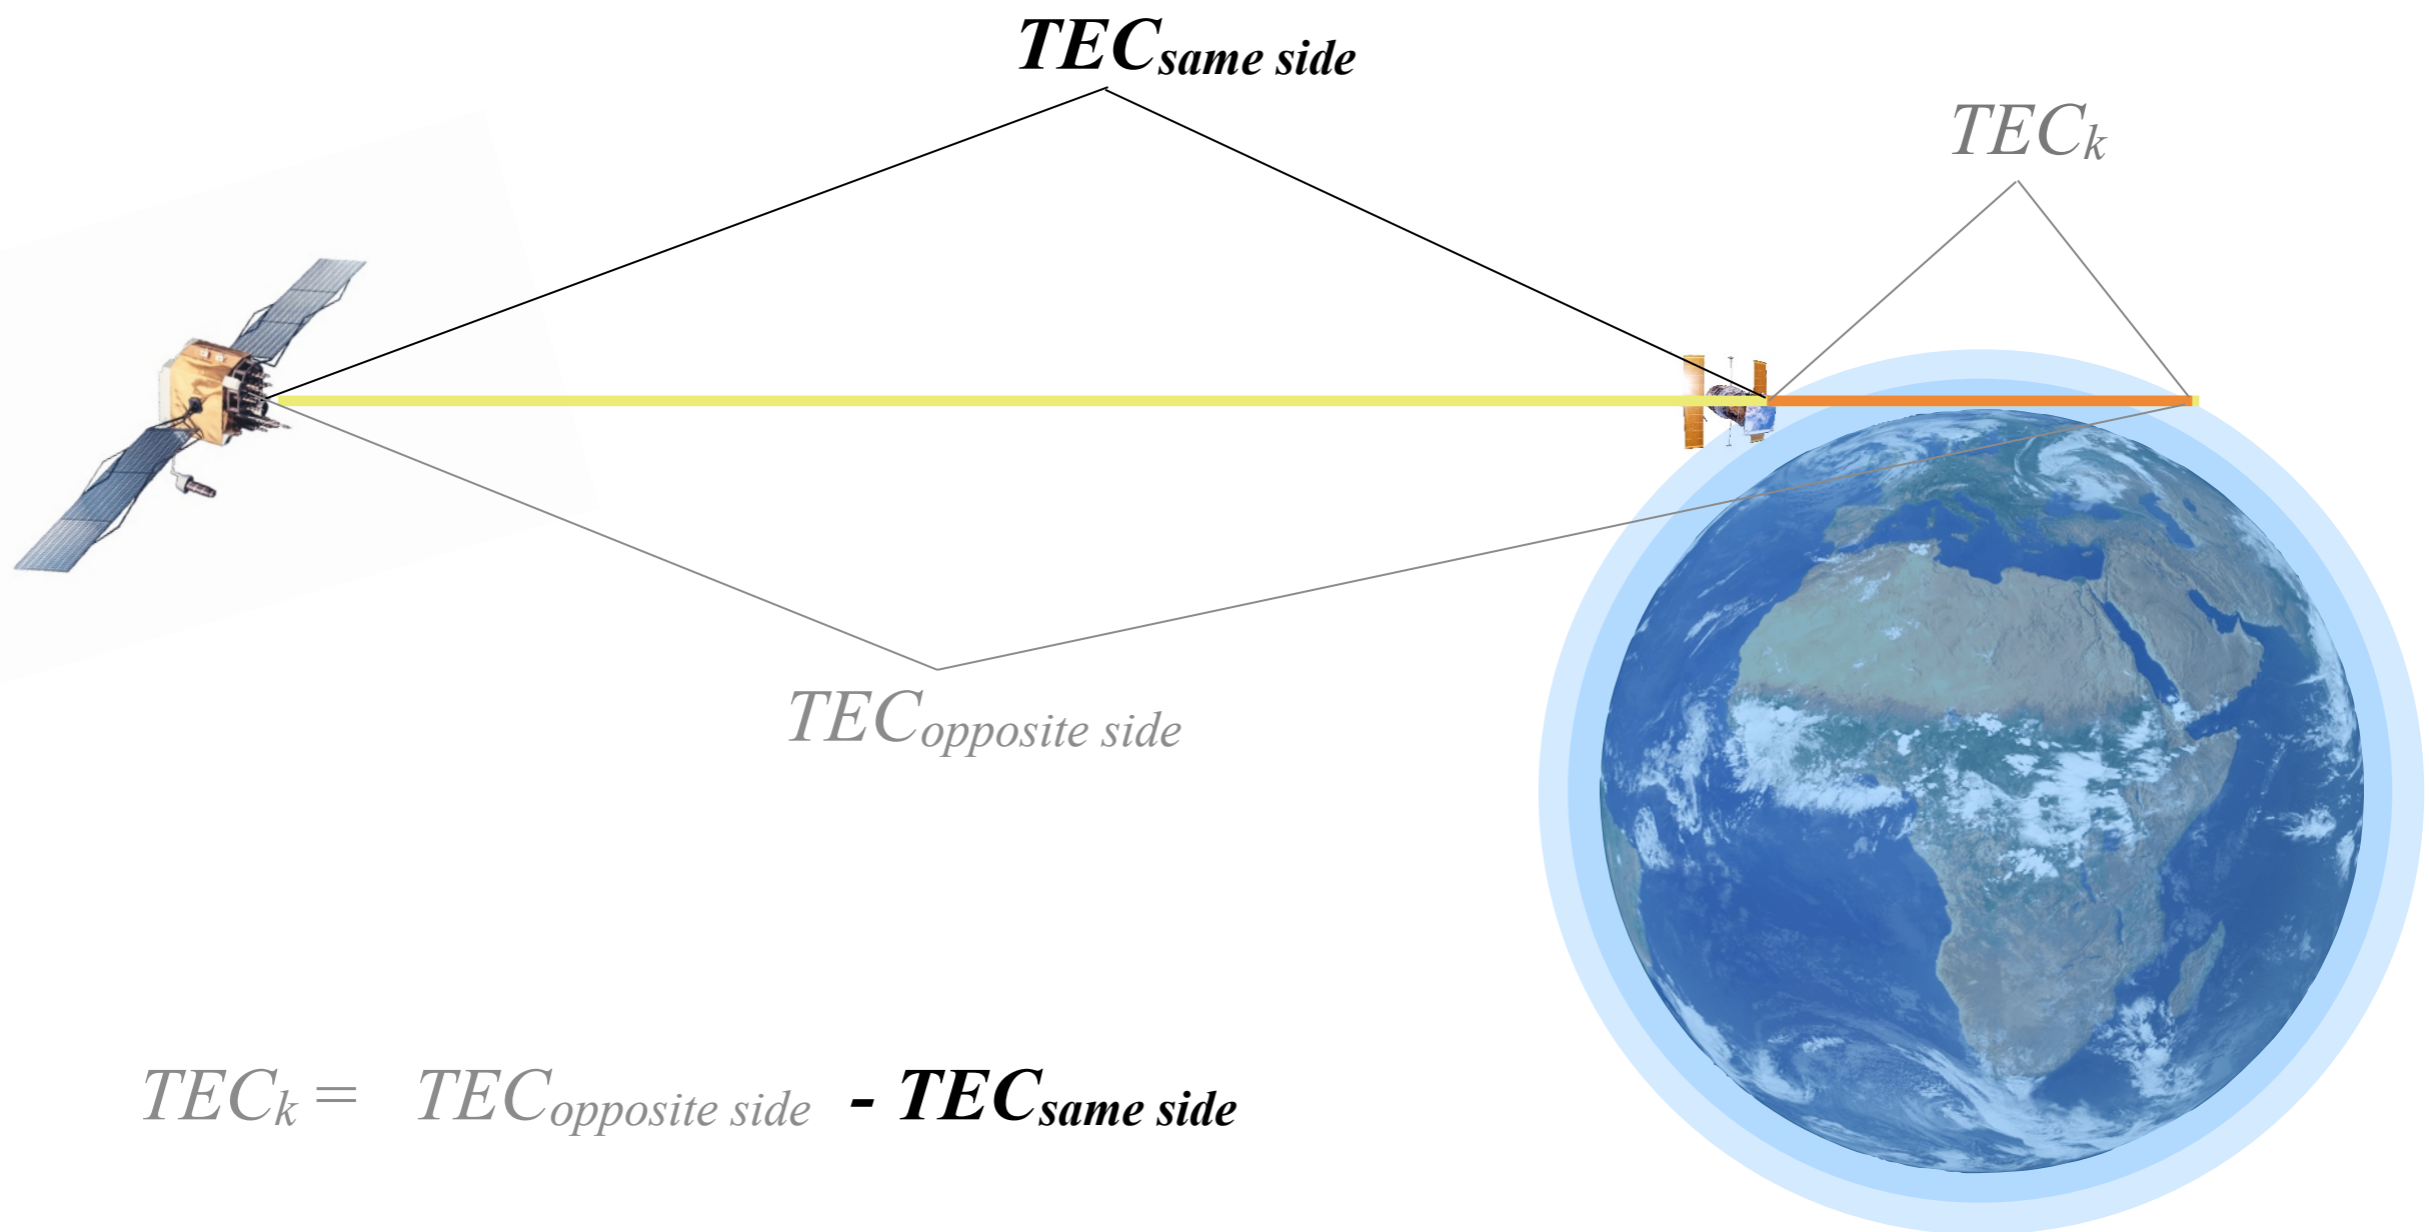

$$TEC_k = TEC_{opposite\ side}$$

TEC calibration

$$TEC_k = TEC_{opposite\ side}$$

TEC calibration

$$TEC_k = TEC_{opposite\ side} - TEC_{same\ side}$$

The role of the “same side” (auxiliary) data in TEC calibration

SIMULATION RESULTS

TEC calibration (COSMIC like sat.)

WITH auxiliary data

WITHOUT auxiliary data

TEC calibration (CHAMP like sat.)

WITH auxiliary data

WITHOUT auxiliary data

The spherical symmetry assumption for the electron density of the ionosphere: effects on the reconstructed profiles.

Plasma “caves”

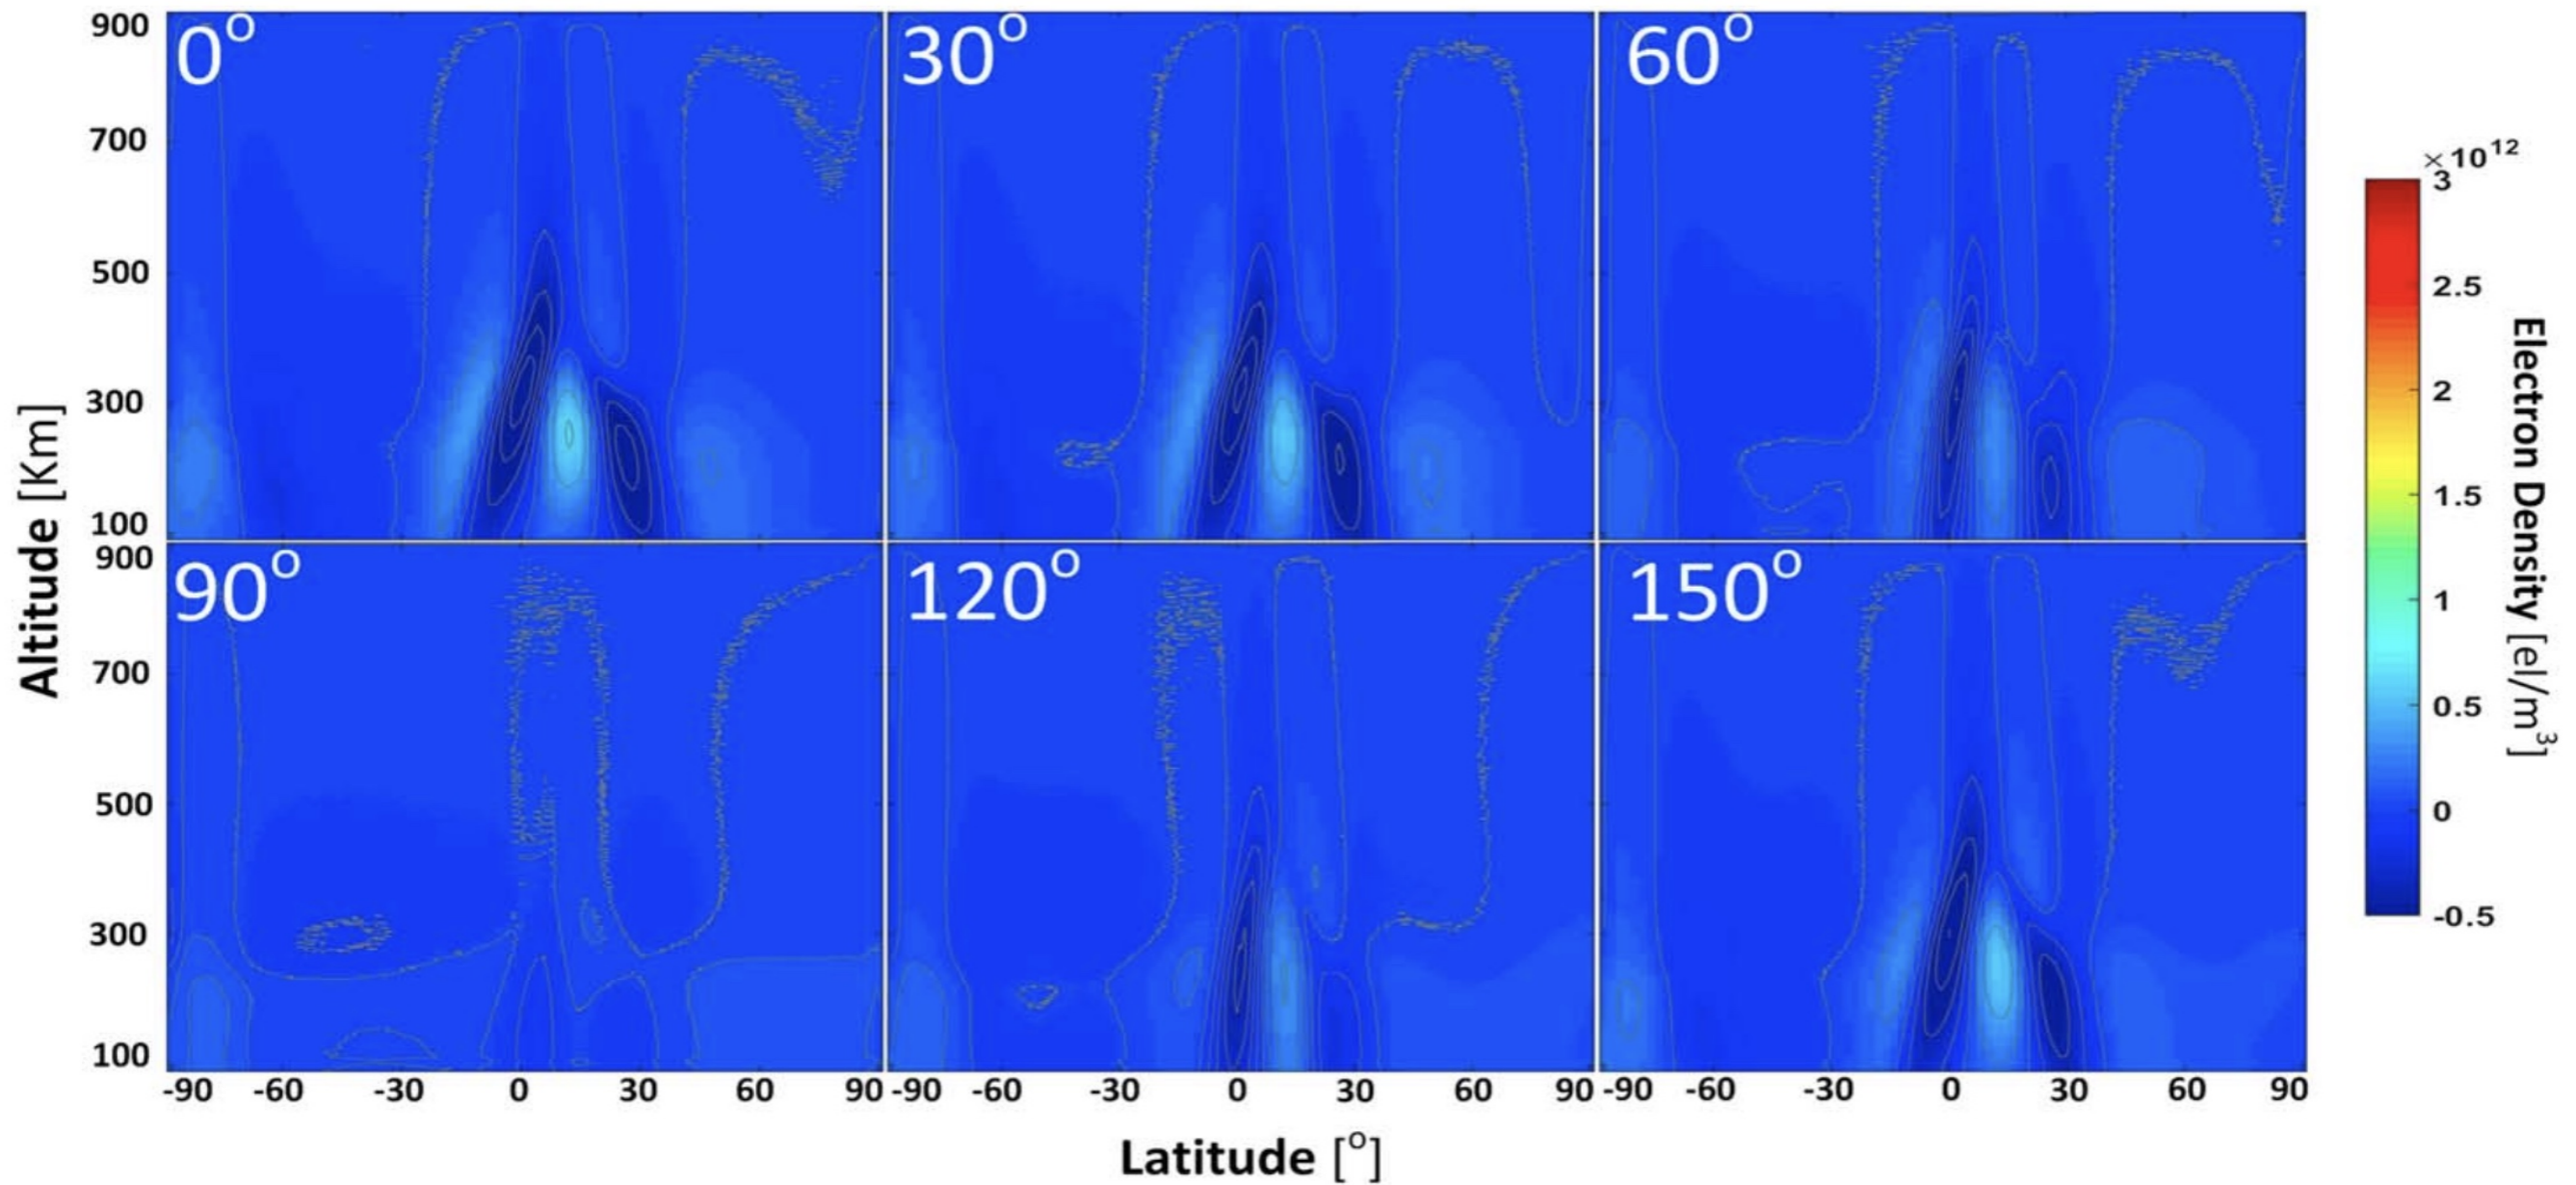

Geomagnetic latitudinal and altitudinal variations of true (NeQuick) electron density (a), retrieved electron density (b), absolute deviation (c) and relative deviation (d) between retrieved and true electron density during 12:00–14:00LT. The unit in panels (a–c) is 10^{11} m^{-3} and in panel (d) is percentage. The intervals between the contour lines in (c) and (d) are $0.5 \times 10^{11} \text{ m}^{-3}$ and 50%, respectively (from Yue, et al., 2010).

Plasma “caves”

NeQuick-based simulation: Ne from Abel inversion for April, 1400 UT, high solar activity conditions. Each of the six plots shows the RO-derived vertical Ne profiles as a function of latitude along the 0°E longitude meridian for a given azimuth of the occultation plane (indicated at the top left corner of the plot). (From Shaikh et. al, 2018).

Plasma “caves”

NeQuick-based simulation: Ne difference Abel inversion - “experimental” for the same conditions as in previous slide. (From Shaikh et. al, 2018).

Model assisted RO data inversion

A model assisted inversion technique based on the adaption of the NeQuick to RO-derived TEC data has been proposed by Shaikh et al. (2018) to mitigate the spherical symmetry assumption effects on RO data inversion, without using external data (such as for example global ionospheric VTEC maps).

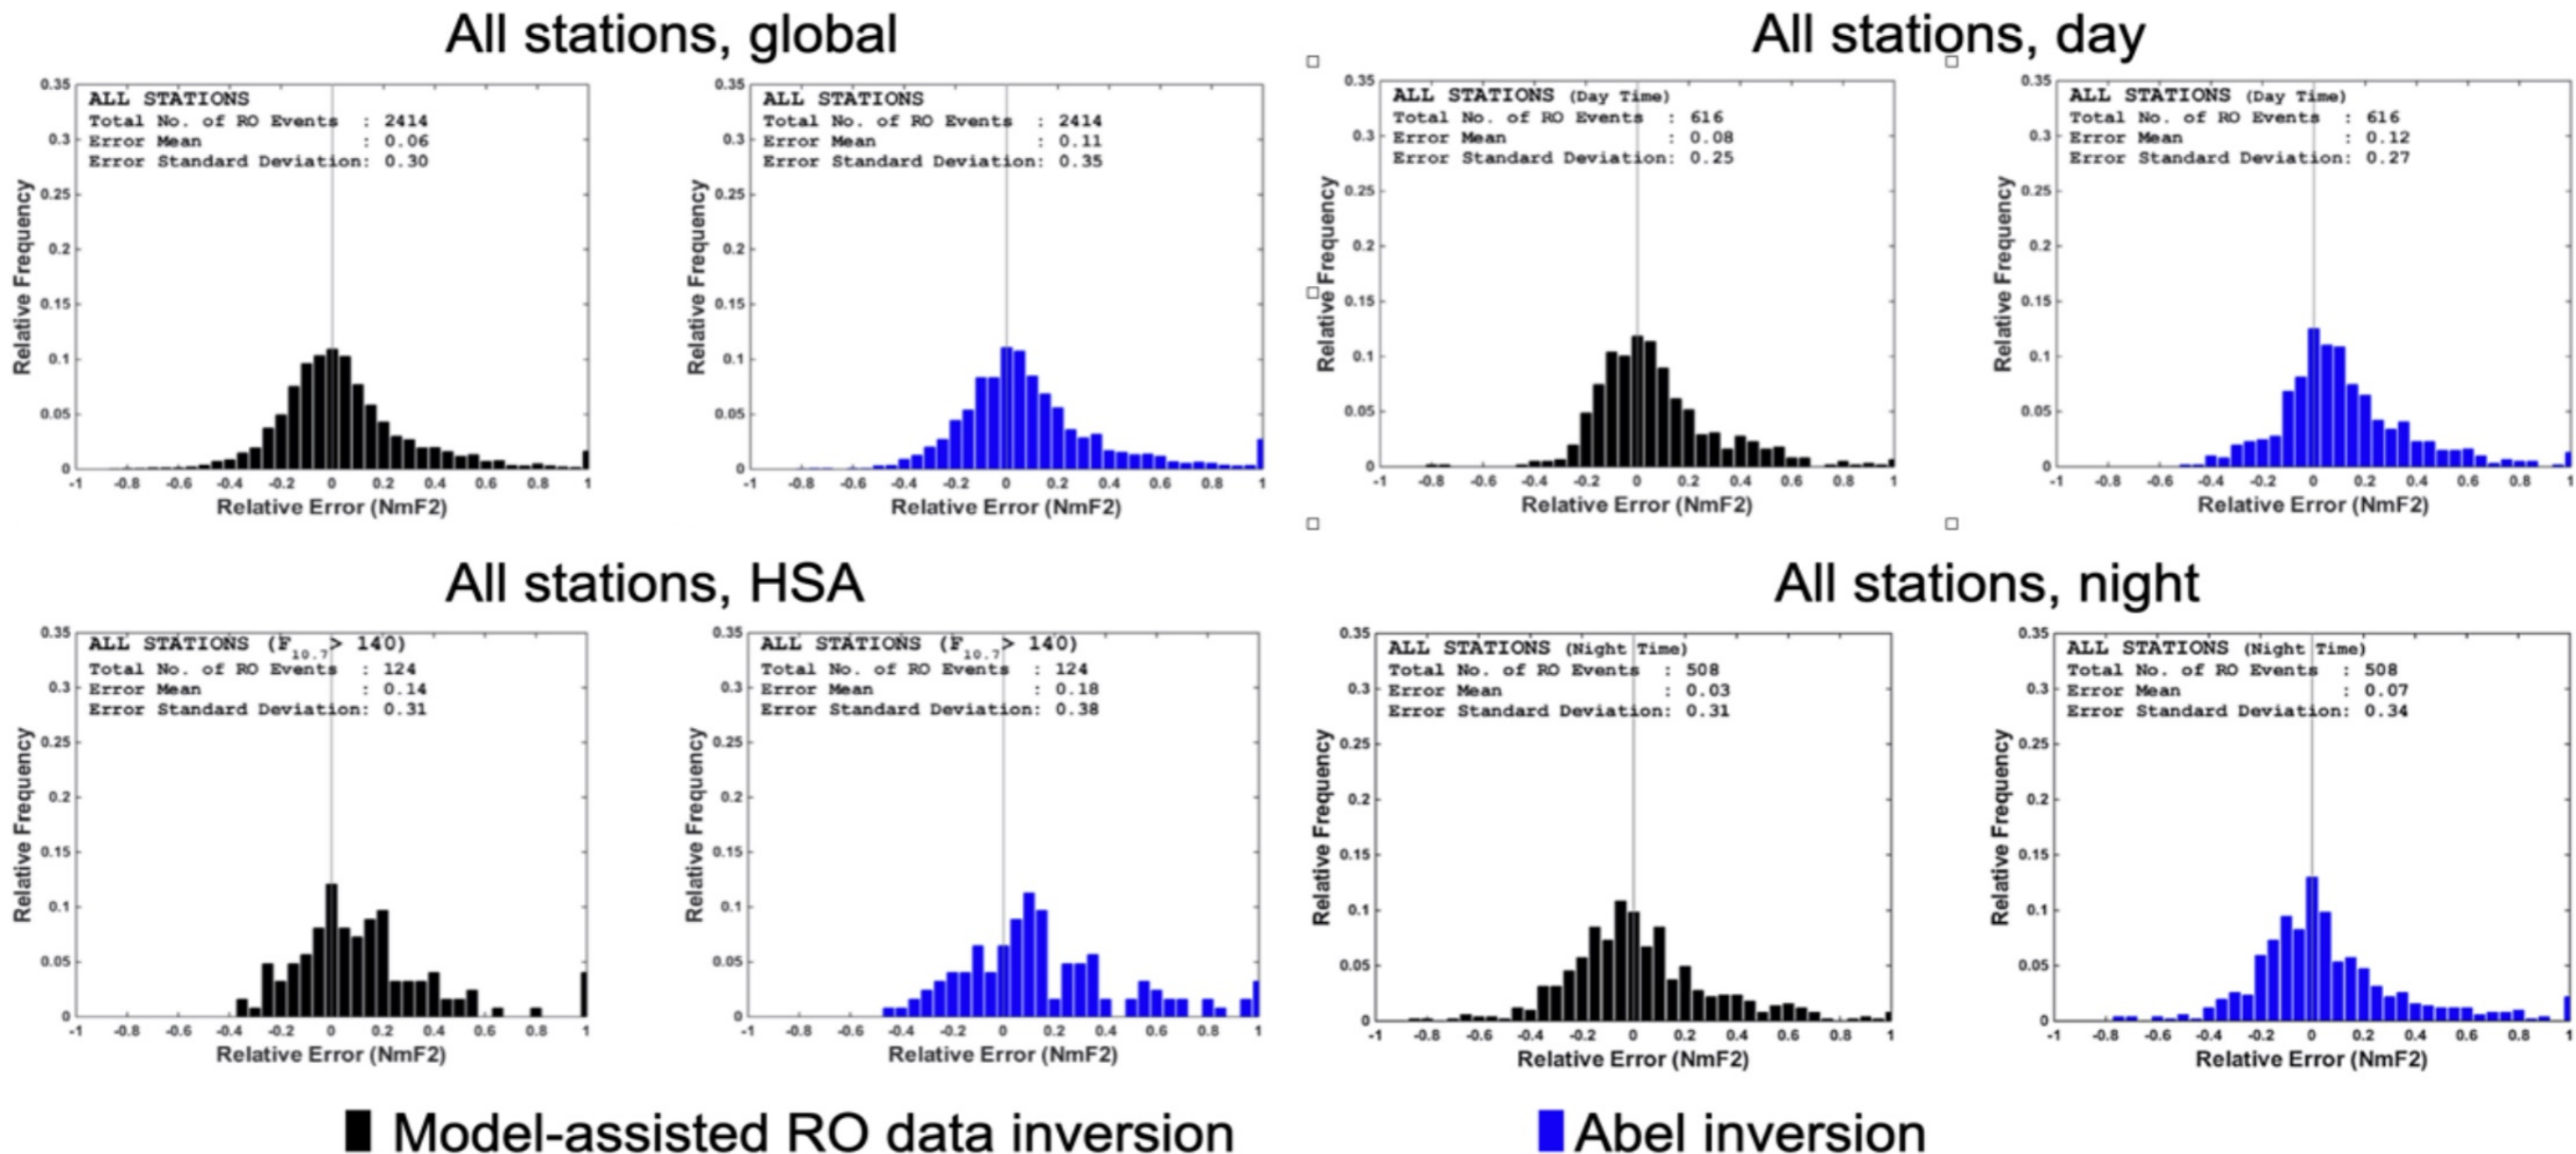

Illustration of spherical symmetry hypothesis for the electron density (left) in contrast to the spherical symmetry assumption of the NeQuick effective parameter $Az1$ (effective F10.7) used to apply the model-assisted inversion (right).

Model assisted RO data inversion

The effectiveness of the method has been quantified utilising the relative frequency distribution of the relative NmF2 errors (period: 01/2007 to 09/2015).

Relative NmF2 error for 13 ionosondes (a), during high solar activity (b), day-time (c), night-time (d). Model-assisted inversion (black); (b) Standard Abel inversion
